THE TIMES AND REGISTER.

A Weekly Journal of Medicine and Surgery.

Published under the auspices of the American Medical Press Association.

WILLIAM F. WAUGH, A.M., M.D., Managing Editor.

VOL. XXI. JULY TO DECEMBER, 1890.

ROYAL COLLEGE OF SURGEONS OF ENGLAND
14 APR 92
LIBRARY

PHILADELPHIA AND NEW YORK:
THE MEDICAL PRESS COMPANY, LIMITED,
1890.

INDEX.

Abdominal pain, 247; section, medico-legal aspect of, 3; sections, 429, 490; surgery, progress, 596
Abortion, double pneumonia complicated by, 564
Abscess, cerebral, 295; hepatic, 179, 228; of ear, 60; of mamma, 360; psoas, 544; pyemic, 37
Accidents from choloform, 42
Acid, trichloracetic, as an astringent and caustic, 296
Acne, ezema, etc., prescription for, 365; vulgaris, treatment for, 11
Acute myelitis, 251; phthisis, 56; tonsillitis, 484
Addison's disease, 250
Adonidin, 179
After-pains, cupric arsenite for, 519
Air-passages, menthol in diseases of, 123
Agaricic acid, 179
Ague, helianthus for, 19
Albumen, new reagent for, 513
Albuminuria, 513; in children, 533; of pregnancy, 153; paraldehyde, a cause of, 532; protides in various forms of, 228
Alcoholic entailment, hereditary, 433
Allegheny County Medical Society, 34, 244, 454
Amateur doctoring, 44
Amaurosis, tabetic, 316
Ambulance work, New York, 462
Amenorrhœa, 297; prescription for, 179
American girls, health of, 592: Medical Journalism, 75; Orthopedic Association, 289
Ammonium mixture, 365
Amœba coli in dysentery, 316
Amputate, when to, 388
Anæsthetics, deaths from, 596
Analine colors in therapeutics, 177
Anasarca by theobromine, 43
Anemia, pernicious, 148; in young women, 30
Aneurisms, 529; treatment of external, 360
Angina, application for, 513; pectoris, 373
Animal parasites, remedy for, 413
Ankle-joint disease, 482, 483; tuberculosis of, 247
Anodyne effects of electric lights, 417; lotion, 225
Anthrax, 90
Antipyretics and fever, 297
Antipyrine, 552; counter-indications, 295; in dermatology, 251
Antiseptic, hydronaphthol as an, 555; midwifery, 286; regimen in contagious diseases, 19
Antiseptics, 469
Antispasmodic, strychnine as, 337
Anus, fissure of, 514
Apoplexy, 40
Aristol, 111, 258, 465, 471; in burns, 573; in gynecology, perscription, 296
Arsenite, cupric, 519
Ascites, 552
Asclepiad, 362
Asepsis, practical, 367
Ashes, preservation of, 87
Asthma, 247; treatment of paroxyms, 333
Asthmatic treatment, 588
Ataxia, Friedreich's, 554
Athritis, gonorrhœal, 514
Atresia of the external auditory meatus, 283
Atropia belladonna and solanum nigrum, 307
Auditory meatus, atresia of the external, 283
Australias "fastness," 151
Babies, sedative for, 464
Baby farming, 530
Bacillary partnerships, 392.
Bacteria, relation of, 49; reproduction of, 511; spontaneous access of, to bladder, 453
Baldwin. J. F., chloroform in obstetrics, 280
Balsams, 14
Barker, T. R., obstetrical don'ts, 561
Baths, cold, in typhoid fever, 227
Beef, dried, poisoning by, 223, 294
Belfield, W. T., operations upon enlarged prostate, 422
Berberis aquifolium, 414
Beri-beri, 492
Berks County Medical Society, 83
Bidwell, W. D., poisoning by dried beef, 294
Biliary fistula, 531
Billings, F. S., preventive inoculation, 185
Birch beer, 60
Birmingham, American doctors in, 225
Bishop, S. S., menthol in diseases of air-passages, 123
Bismuth lotion, compound, 416
Black eyes, 513
Black fever, 19
Black rot, 151
Blackwood, W. R. D., chloroform in obstetrics, 333; progress in medical and surgical electricity, 279
Bladder, spontaneous access of bacteria to, 453
Blindness, total, following shock, 466
Blood cells, new, 366
Blubaugh, C. B., removal of dislocated crystalline lens, 199
Board of Health, Philadelphia, 510
Bone-grafting, 315

Boils, microbous, 594
Borborygmus, voluntary, 90
Boric acid for tuberculosis, 250
Bougies, use of, 360
Bovine blood, and meat juice, in therapeutics, 285
Bright's disease, case simulating, 573
Bright's disease, treatment of chronic, 388
Bromide and iodides by enema, 512; of ethyl, 90
Bromides in epilepsy, 555
Breath, bad, mixture for, 416
Bromole, 367
Bronchitis, chronic, 225; phenacetin in, 11

Broncho-pneumonia, chronic, 290
Brown-Séquard mixture, 153
Bruises, for recent, 225
Bubo, 588
Bubos, gonorrhœal, parenchymatous injections of iodine for, 221
Bunion, operation for, 251
Burdock seed, elixir of, a menstrual regulator, 314
Burns, aristol in, 573; prepared cotton for, 297; treatment of, 296, 513, 529
Cæsarian section, 529
Calomel as a diuretic, 204; toxic effect in the presence of chlorides of the alkaloids, 392
Cancer, deaths from, 204; of stomach, 1, 338, 579; pathology of, 397
Cannabis indica for dyspepsia, 226; for neurosis and gastric dyspepsia, 311
Capsicum, tincture of, 524
Carbuncle, gangrenous, 552
Carcinomata mammæ, 9
Cardiac ossification, 391
Caries, Potts' spinal, 66; dental, mixture for, 114; of teeth, transmission of, 335
Cascara amarga, 90, 152; wine of, 296
Castration in women, 364; nervous symptoms due to double, 130
Cataract extraction, intraocular syringing in, 204; immature, 591; resorption of immature, 565
Catarrh, gastric, 1, 274, 513; of naso-pharynx and middle-ear, surgical means applied to, 121
Catha edulis, 415
Catheter fever, 112
Catskills, 175
Cattle, tuberculous, 66
Census of 1890, 550
Cephalo-hematoma, 38
Cerebral abscess with epilepsy, 295; hemorrhage, 130
Cervix, amputation of, 9
Chancroids, phagadenic, 546
Chattanooga, 225
Cheatham, W., massage of middle ear, 250
Chicago Academy of Medicine, 325
Chigger, 550
Childhood, disease of in relation to tubercle, 67
Children, albuminuria in, 533; digitalis in diseases of, 364; diseases of, 359; nourishment of, 16; summer disturbances of, 113
Chinese remedy for diphtheria, 290
Chloralamid, administration of, 392; formula for, 416
Chloroform, 392; accidents from, 42; death under, 514; in obstetrics, frequent use, 9, 280, 333
Cholecystotomy, 6, 421
Cholera infantum a neurosis, 73; in Mecca, 129; morbus, prescription for, 225; new treatment for, 176; salol in, 90, 464
Chorea, 566
Chromic acid for perspiring feet, 153; in cysts, 60
Chronic dyspepsia, 314
Chyluria, 338
Cigarette, accident caused by, 311
Cincinnati, letters from, 312, 440
Circumcision, 37
Clevenger, S. V., Chicago Academy of Medicine, 325
Climate and disease, 247; or weather fever, 62; therapeutic value of, 514
Coagulating process, 408
Coal oil, 59
Cocaine anæsthesia, 14; in short operations, 91; ptyalism of pregnancy, 226
Cocktail, gin, 13
Coffee, uses of, 366
Coimbra, University of, 109
Coinage and infection, 510
Cold, to break up a, 224
Color-blindness, alcohol and tobacco causes of, 152
Conjunctivitis, subacute, 247
Constipation, chronic, 532; diarrhœa of, 574; treatment of habitual, 512
Continuous bath for typhoid fever, 87
Convulsions in chlorosis, treatment of, 333; puerperal, 34
Convulsive, acute, seizure, the result of a fish bone in the rectum, 229
Cornea, suppurating ulcer of, 308
Corneal disease, galvano-cautery in, 467
Coryza, menthol in, 115
Cough mixture, 225; of nasal origin, 428
Country doctor, 223
Coxalgia, 26
Cranium, fracture of, 15
Creasote in the treatment of diseases of the respiratory organs, 295
Cremation, 13
Crime, study of, 329
Crothers, T. D., American medical journalism, 75; inebriates, 126; inebriety in America, 144
Currier, A. F., anemia, 30
Cutter, Ephraim, food and tubercle, 378
Cystitis, 57, 180; in women, 91
Cysts, chromic acid in, 60
Cysts, serous and cystic formations, 399
Deafness, traumatic, pilocarpine for, 17
Deahofe, L. F., pneumonia, 125
Death, test for, 514
Delirium, 311; tremens mixture, 153
Delstanche instrument for massage of middle-ear, 250
Dental caries, mixture for, 114
Dentifrices, antiseptic, 364
Dermatitis, excretal, 467; herpetiformis, 163; multiformis, 217
Dermatology, antipyrine in, 251
Diabetes, case of, 578; formulæ for, 392; insipidus, 179; is it contagious? 204; mellitus, 233; sulphonal for, 337, 487
Diabetics, diet for, 596
Diagnostic tables, 180
Diarrhœa of constipation, 574; morning, 85; prescription for, 333; summer, in adults, 179; tropical, 111
Dietetic problem, 15
Digestion, pancreatic, in marasmus, 393
Digitalis, 464
Diphtheria, 221, 597; and scarlet fever, prevention of, 549; antiseptic tincture for, 513; Chinese remedy, 290; etiology of, 53; from animals, 468; identity of human and animal, 442; local application for, 365; of meatus urinarius, 152; potassium iodide in, 579; puerperal, 37
Diphtheritic membrane, 226
Dismenorrhœa, obstructive, 113
Diuretic and drastic, 416; calomel as a, 204; formula, 416; third plague of Egypt as, 362
Doctor, country, 223; habits of, 550
Doctoring, amateur, 44
Donnellan, P. S., tincture of capsicum, 524
Douglas' cul de sac, operation, 566
Drinks, summer, 61
Dropsy, cardiac, remedy for, 333
Drugs, exact doses for, 488
Drunkenness, what is it, 304
Dunlap, W. H., dermatitis multiformis, 217
Dwight, H. E., medical education, 566
Dysentery, amœba coli in, 316
Dysmenorrhœa, 179
Dyspepsia, 472; atomic, 484; canabas indica for, 226
Dyspnœa, fatal, 442
Ear, abscesses of, 60; middle, catarrh of, 519
Earache, mixture for, 115
Ears, operation for prominent, 514
Eastlake, W. de Lano, sulfonal, 261
Eczema, acute, formula for, 413; encrusted, 36; formula for, 416; infantile, 36, 360; of hands, prescription, 290
Eclampsia, puerperal, 250, 314, 367
Epilepsy, trephining for, 596

CANCER OF THE STOMACH. GASTRIC CATARRH WITH DILATATION, AND ACUTE NEPHRITIS. MITRAL DISEASE.[1]

By W. E. HUGHES, M.D.

I HAVE here the history of a gentleman, aged forty-seven years, and a mulatto, who has no family history bearing on his condition, while his own previous history is negative. Nine months ago he began to have pain in the stomach, more especially in the morning, which was more or less continuous. He vomited, and eating increased the pain, which was most marked on the left side, and would shoot through the abdomen. He has lost fifty pounds in the last two months. The prominent symptoms in the case at that time were those of gastritis, with pain in the stomach, which was rapidly succeeded by vomiting, and which was increased by taking food. He has lost flesh and has assumed a yellow color, due to anæmia and cachexia. It is difficult to say how much cachexia is present in a mulatto, on account of the color of his skin. The vomiting occurred at irregular intervals; the amount was not large, and was of a bilious character. In cases of cancer of the stomach, the vomiting occurs at regular intervals, and consists of undigested or partially digested food, and may be days after the food was taken. Here we did not have this characteristic vomiting. The pain, however, was more marked than the pain of ordinary gastritis, and, although the pain of gastritis is more marked after the ingestion of food, this case had more or less constant pain, accompanied with a loss of flesh and profound anæmia. On palpation, there seemed to be, in the median line, over the stomach, an increased resistance—no actual tumor—that was so pronounced that it led us to make the diagnosis of cancer of the stomach. The fact that the vomiting was not characteristic of cancer led us to think that it was within the walls of the stomach, in place of the inner surface of the pylorus. The pyloric end of the stomach is dilated, hence the vomiting. When cancer occurs in the walls, there is, as a rule, no dilatation.

The man died of asthenia, and, on post-mortem, we found an infiltrated, ulcerating growth on the side of the stomach; the pylorus remained patulous, and food could pass through. The cancerous growth was adherent to the right lobe of the liver, and had ulcerated into the structure of the liver, and, at one point, had almost perforated the peritoneal cavity, in which case it would have caused an abscess in place of general peritonitis. There seems to be nothing in the case to account for the increased resistance felt on palpation. The man had an unusual amount of pain for cancer, and had several attacks of gastralgia. A small abscess was found between the colon and the abdominal wall. The liver was drawn up under the ribs, which was rather unusual. You can see that this case demonstrates the fact that we may have cancer of the stomach which is adherent to the surrounding viscera, and not detect the presence of a tumor on examination. When felt, the tumor is most commonly found in the epigastric region, but you will meet with cases where a diagnosis must be made without the presence of a tumor being detected.

CHRONIC GASTRIC CATARRH WITH DILATATION.

I wish to bring before you a patient who has the symptoms of gastric cancer, but I do not think he has this disease. We have had him under observation sufficiently long to make a diagnosis of the case.

[1] Delivered at Philadelphia Hospital, May 10, 1890. Reported by W. B. Stewart, M.D.

This man claims to be ninety-one years of age; family history is negative; had good health until three years ago; has been a moderate drinker, and has no specific history. Three years ago he was subject to attacks of epigastric pain, and began to vomit. His diet was regulated and his trouble ceased, but soon began again. At times he would go for several days without vomiting. He was admitted to the hospital on September 24, 1889, and his condition now, is, practically, what it was at first. His prominent symptoms are referred to his stomach; appetite is poor, but, from the amount of material he vomits, he must force himself to eat. After he eats, a distinct pain occurs in his epigastrium. He seldom vomits immediately after eating, but does so later. The vomited matter is partially digested food that has been taken several days previously. The attacks of vomiting are severe, and he gets up some reddish-brown matter after he has made several attempts. His general condition has not failed, while his complexion remains fairly good. His tongue is fissured, and coated, like it is in cases of chronic gastritis. The abdomen, on percussion, is more tympanitic than it should be,—all over the epigastric region and below, the percussion note is the same. The point to determine is, if this tympany belongs to the stomach. This is often difficult to determine, for the colon often becomes so distended with wind that you cannot tell where tympany of the colon begins, nor where it ends. If the tympanitic note found thus low down is that of the stomach, it is a case of dilatation, and all the symptoms point to this condition. A distinct succussion splash can be heard, and it is now four hours since he has taken food or drink. Shaking can only cause a sound when the stomach is dilated with air. On looking at this man's abdomen closely, I fancied I could see a distinct vermicular action of the stomach. We have in this case, in addition to the chronic gastritis, vomiting that is not influenced by food; the presence of increased tympany over the stomach; the presence of splashing sounds,—all of which point distinctly to dilation of the stomach.

I will go further to demonstrate the diagnosis. We can give substances to be taken into the stomach to cause gas which will dilate it to its full capacity, and, as a rule, we find this a positive diagnostic sign. I have here prepared two Seidlitz powders. I will let him drink the alkaline portion first, and then the acid. Percussion now shows that there is marked tympany which has increased over the area of the stomach. The fact also that he can contain the amount of gas generated from two Seidlitz powders, without discomfort, is in itself an indication of dilatation of the stomach. As I stated, gastric carcinoma is a great cause of dilatation, but in six months' time there is no cachexia or anæmia, nor any tumor, so that I think we can say that there is no cancer present. Fibrous degeneration of the walls of the stomach with infiltration will give rise to dilatation, if it obstructs the pylorus; but I do not think this is the case, for the vomiting is not marked enough, and the bowels are not sufficiently constipated. In addition to these causes, dilatation of the stomach is caused by an atonic condition of its walls from a long continued gastritis and the ingestion of all forms of food. There is evidently a marked catarrh of the mucous membrane of this man's stomach with congestion.

Now, a few words as to treatment. In the first place, he has in his stomach a large amount of iritating mucus, and the first thing is to get rid of this. Nature attempts this by vomiting, but the walls of the stomach are too weak to do this satisfactorily. We can remove this mucus by introducing a gum-tube through the œsophagus into the stomach; pour warm water through it into the stomach until it is full; depress the end of the tube, and thus empty the stomach by syphon-action. Repeat this until the return-flow is perfectly free from mucus. Here there can be no relief except from such a treatment. When the tube is introduced, depress it well against the posterior wall of the pharynx, and ask the patient to swallow as you introduce it into the stomach. You see that in this case the matter drawn from the stomach consists of a stringy mucus that is smeared over the mucous membrane, and acts as a mechanical hindrance to the action and flow of the gastric juice. If you have a case where there is great irritability, get the confidence of the patient, and persist, and in time it will be overcome. In place of pure water you may use some antiseptic solution, such as salicylic acid, thymol, creoline, creasote; or some alkaline solution that will stimulate the stomach more than antiseptics. If there is marked dilatation, this washing process should be done every day, but in this case it is done every four days, and as the patient improves the time will be lengthened. Good results will not be shown for the first week or more. After one of these washings you will find that the digestion will be improved; the bowels that have heretofore been constipated become regular. In addition to this we will treat the gastritis by the mild astringents, such as bismuth, or nitrate of silver, or something of that kind. Probably the use of mineral acids is good. In addition to the treatment of the mucous membrane, we must treat the muscular coat by the employment of such agents that will restore the muscular tone. The most valuable agent at our disposal is strychnine. A faradic current of electricity has been used, by applying it to the abdominal walls with the hope that it would affect the stomach. Some advise the passage of an electrode into the stomach, but I have had no experience in this treatment. Massage over the stomach is a valuable agent. Pay strict attention to the general health and diet, and put the patient under the most favorable hygienic surroundings. This man reports himself as very much improved under this treatment. After all, when we come to sum up all forms of treatment for dilatation of the stomach, the washing process is the best.

ACUTE NEPHRITIS—MITRAL DISEASE.

Our next patient is a man twenty-five years of age, who has a good family history. Seven weeks ago he had his leg injured by a sledge-hammer. Following this, he was seized with dyspnœa, so that he could not lie down at night. The dyspnœa has only been present for a few days. His feet began to swell. In depraved conditions of the blood œdema begins in the dependent parts of the body, extends upward and finally invades the whole body; such a condition may occur in profound anæmias, or in phthisis. Œdema may be due to an obstruction in the return flow of blood through the veins; to heart or kidney disease. This man's urine was examined and it was found to contain albumen, numerous granular casts, and is evidently the urine of a diseased kidney. Until two weeks before this attack, he says, he was perfectly well, except that he would have to get up once or twice during the night to pass his water. I find a moderate amount of fluid in both pleural cavities. There is no inflammatory condition of the pleura. Looking at this man, we can see a distinct pulsation about the root of his neck, and

notice the artery beating on the left side, which should direct our attention to the aortic valve of the heart. On examination, I find no lesion of the aortic valve, but there is a stenosis and deficiency of the mitral orifice. Here then is a lesion that must have existed for years without this man knowing it. It is probably due to the result of one of the exanthemata of his childhood, for he has no rheumatic history. This cardiac weakness predisposes him to accidents. There has been set up an acute nephritis in this case. We get the symptoms of cardiac disease due to a disturbance of the equilibrium of the circulation by the acute nephritis.

Treatment should not be directed so much to the heart as to the kidneys, for they are the organs that disturb the circulation, and I think that by treating them, the dyspnœa will disappear, and he will be restored to his usual health and may live for years. Heart trouble may be brought into prominence by some small acute trouble, and we cannot hope for any good results, until it is relieved. In any case of this kind, do not treat the heart trouble, but anything that will disturb the heart must receive attention. A heart of this kind is not incompatible with a long and useful life.

THE MEDICO-LEGAL ASPECT OF ABDOMINAL SECTION.

By A. VANDERVEER, M.D.,
Professor Didactic, Abdominal and Clinical Surgery, Albany Med. Col.,
ALBANY, NEW YORK.

A YEAR ago I had the pleasure of presenting to the Section on Obstetrics and Diseases of Women and Children, American Medical Association, a paper on Concealed Pregnancy, and its Relation to Abdominal Surgery. In the preparation of that paper considerable time was devoted to the compiling of a table of cases wherein abdominal section revealed an undiagnosticated pregnancy. This table is measurably complete, and journals, by extracts and summaries, have given a wide circulation to the paper and the table. While that table was in preparation, from letters and other sources, my attention was called to the medico-legal aspect of abdominal surgery, in its general relations, and to the probable testimony of expert witnesses in the cases where an action for malpractice is brought. For this and the other reason that two American surgeons have already been compelled to plead to an indictment of manslaughter, it seems to me profitable to join this paper rather as a supplement to the one of last year, by considering certain medico-legal points of abdominal surgery. A letter from a very eminent American surgeon in relation to one of these cases says, "For my part I do not see how the error occurred." And I have numerous other letters, stating that we ought never to be unable to diagnosticate pregnancy, especially after the fourth month. Testimony such as this would have been very dangerous to such men as Professors Freund, Karstrom, Wm. Varien, Czerny, Byford, and others equally as competent, had they been placed on trial for malpractice.

We all may, at any moment, be placed upon our defense by clamor of the public press, which seldom, very seldom, gets down on the right side of any medical question. Dr. Mary A. Dixon-Jones is a conspicuous example of newspaper persecution, which, happily, she overwhelmed. Designing attorneys, with prospects of good fees, may urge unwilling people into litigation, or, avaricious relatives may, failing in levying blackmail, institute an action. Motives no different than these give rise to nine-tenths of all action for malpractice.

In case of the death of the patient the surgeon may be proceeded against, criminally, by an indictment for manslaughter, and civilly, an action for damages. One action criminal, is no bar to another civil, for damages, nor can the result in one prejudice the result in the other. If the surgeon be proceeded against by indictment in my State, New York, the indictment is drawn under the provisions of the Penal Code, Section 195, viz.: "A person who, by any action of negligence or misconduct in a business or employment in which he is engaged, or by any unlawful negligence, or reckless act, occasions the death of a human being, is guilty of manslaughter in the second degree."

In States where no statutory provisions have been enacted, the indictment is drawn at common law. At common law, "If a physician or surgeon, or any person assumed to be such, by his gross negligence, or gross ignorance, or by his rashless or want of proper caution, causes the death of his patient, it is manslaughter." (Field's Medico Legal Guide).

As the statutory provision is drawn from the common law, and depends for its interpretation on the interpretation of the common law, we can find no clearer demonstration than that of Lord Ellenborough (Rex *vs.* Williamson, 3 C. & P. 635), in his charge to the jury. He says: "To substantiate the charge of manslaughter the defendant must have been guilty of criminal misconduct, arising either from the grossest ignorance or the most criminal in intention. One or the other of these is necessary to make him guilty of that criminal negligence and misconduct, which was essential to make out a case of manslaughter. It does not appear that there is any want of attention on his part, and from the evidence of the witnesses on his behalf, he possessed some degree of skill." (The defendant in this case had forcibly torn away a prolapsed uterus, following delivery.) "I think the defendant could not possibly commit such mistakes in the exercise of his unclouded faculties, and I own that it appears to me that if you find the prisoner guilty of manslaughter, it will tend to encompass a most important and anxious profession with such dangers as will deter reflecting men from entering into it." (The verdict not guilty was entered in this case.) As far as I am able to learn, charges to juries have been uniformly that gross neglect, or gross ignorance, or both, must be shown on the part of the prosecution beyond a reasonable doubt, before a conviction can be had. Then, as has already been shown, the prosecution must stand or fall upon the proof of gross negligence, or gross ignorance, one, or both, or, in other words, criminal misconduct. Gross ignorance and gross negligence are both questions of fact, and must be passed upon by a jury. In consequence, the standard of care and skill must form that, and other facts and conditions, but must be a variable one, as they are not questions of fact purely. It is the duty of the court to charge the jury with reference to degrees of care and skill by definition and illustration. It has been maintained that it is impossible to make precise distinctions between negligence and gross negligence. Mr. Justice Bradley (U. S. S. C. Reports) says: "In deciding the question of negligence where there is any conflicting testimony, and ordinarily where there is not, all the facts and circumstances should be submitted to the jury, with instructions that in deciding whether there was ordinary care or gross negligence, they are to con-

sider the position of the party, his business, his duties and responsibilities, and that the same act which, under some circumstances, would not show any degree of negligence, might, under others, show want of ordinary care; and, under still other circumstances, might show gross negligence, and this should be settled by the jury as a question of fact, and not by the court as a question of law."

Gross ignorance is open to the same objection that gross negligence is, viz.: of being relative. That which, under some circumstances, would be ordinary skill, in other circumstances would be ignorance; and, in still other circumstances, would be gross ignorance. The very favorable rule of law has been laid down that "The least amount of skill, therefore, with which a fair proportion of the practitioners of a given locality are endowed, is taken as a criterion by which to judge the physician's ability or skill" (Bouvier's Inst., 1,004–5). "The surgeon must adopt the means and apply the skill well settled by the highest lights of his profession. He must possess and practically exercise that degree and amount of skill, knowledge and science which the leading authorities have pronounced as the result of their researches and experience up to the time, or within a reasonable time before the issue or question to be determined is made." (Elwell on Malp. 55).

Surgeons residing in the large cities, with hospitals and other superior advantages, will be required to possess greater skill than those living in localities remote from such advantages; and there seems to be a concensus of judicial opinion that, unless specificially contracted for, the surgeon is only bound to exercise the ordinary care and skill.

By way of illustration, let me present a single case, the kind of which is not likely to occur again. Surgeon A. is called to a case of abdominal tumor. By examination he finds that the patient is thirty-six years old, married twenty years, no children. The tumor had been growing eight months; she has vomited and been constipated at intervals; has felt no quickening, and does not believe herself pregnant. Vaginal examination reveals a cervix high up, somewhat enlarged, os uteri not patulous or particularly softened, unable to make out body of uterus. Upon abdominal examination a distinctly fluctuating tumor is made out, located centrally and, evidently, from the physical signs, contains fluid within a cyst. The diagnosis of ovarian cyst is made, and an operation proceeded with. Upon opening the abdomen the tumor appears. The walls are thin and not of unusual appearance; the trocar is introduced, and six quarts of fluid withdrawn, after which the operator finds he has tapped a pregnant uterus. He completes the operation by Caeserian section, and in five days the woman dies of septicæmia. Surgeon A. is indicted for manslaughter, the indictment averring that he, through gross ignorance, by gross negligence, by rashness or want of proper caution, caused the death of his patient. The indictment is drawn under the provisions of the common law of the State in which he resides. Surgeon A. pleads not guilty, and the trial is proceeded with. The prosecution prove the facts as have been heretofore stated, and call expert witnesses to prove gross ignorance, gross negligence, want of caution or rashness. The only way they can demonstrate the facts so essential to conviction is by expert testimony. The chief question involved and presented with earnestness, Was there sufficient symptoms of pregnancy present to arouse the suspicious of pregnancy, and did the defendant exercise sufficient care and skill in making his diagnosis? The opinion of the witnesses for the prosecution is that sufficient symptoms, amenorrhœa, vomiting, and the presence of a tumor was sufficient evidence of pregnancy to require a most searching examination before pregnancy could be excluded, and that the defendant was negligent and unskilful in his examination. It is shown that he did not examine the breasts for the changes that occur in pregnancy; that he did not inspect the vagina for the change in color (wine-leaf); he did not seek to elicit ballottement; and he did not lay sufficient stress upon these and other symptoms as to the probabilities of pregnancy; and that a proper explanation of the possibilities of her condition was not made to the patient and her friends previous to the operation; that no suggestion was made by the operator as to the necessity of exploratory incision, if at all in doubt as to diagnosis.

The defendant showed by competent witnesses that he had exercised the average care and skill in examining the patient; that he had not acted with undue haste or rashness; that he was honest in his belief that the case was one of ovarian cyst. He admitted having committed an error of judgment, and which he believed was liable to occur in the hands of surgeons of good reputation under existing circumstances. The case was ably tried, and the jury brought in a verdict of guilty. It was carried to the next court, and there the court, on argument, overruled the verdict, presenting some very strong points on the subject; part of the line of argument being that the surgeon was shown to have been a man of great experience, of large practice; a man who stood extremely well with his professional brethren, who had for years maintained a high reputation—very far above the average. That the verdict rendered by the jury was not for the public good, and that the conviction ought not to stand. No farther attempt was made by the prosecution.

Another case which illustrates ninety-nine per cent. of the cases of concealed pregnancy, where an operation has been done, is surely not so easy of diagnosis, being that of Surgeon B., having a patient aged fifty, married many years, always sterile. Fibroid had existed for twenty years or more—a pregnancy not suspected. A hysterectomy was done for the removal of the fibroid, and when the uterus was opened, to his own and everybody's surprise, the surgeon brought out a buxom fœtus, which seemed also very much surprised, for it immediately began to cry. It proved to be at least eight months old and all right. There was also a very large fibroid, which was very vascular. Unfortunately, the patient died soon after. Surgeon B. was tried for manslaughter and acquitted.

Perhaps one of the most unpleasant cases of malignant persecution is the case of Surgeon C., where, after careful explanation to the patient of the physiological change that would take place, and her condition after the operation, it was finally decided to remove the uterine appendages. The operation was done, the patient recovered, and some months afterward a suit was brought against Surgeon C. for willful mutilation. It was shown that all proper explanation had been made to the patient and to her friends, that the operation had been skilfully done, and the patient made a good and speedy recovery, and yet the jury disagreed. A second trial took place some time after, and the surgeon was acquitted, yet he had been to great expense in his defense, and had lost much valuable time; but the laws of his State afforded him no redress whatever. I might cite other cases, but can say earnestly, and for the comfort of the

honest and well-meaning surgeon, that I have not been able to find a case where conviction has occurred and the higher courts have sustained the verdict. A careful study of the rulings of the courts and charges made by judges to the juries in such cases, brings up prominently the fact that the law recognizes no one school in medicine. The doctor must practice the necessary skill in the diagnosis of his cases, and he must exercise the average degree of ability in the doing of the operation, and that he is not supposed to do more than is required of the person possessing an average amount of skill. Another point that seems to have been presented with considerable force by some of the rulings, is negligence on the part of the plaintiffs. In several operations it was shown that the plaintiff wilfully withheld from the surgeon certain symptoms, and that she purposely misled him by making statements of conditions that really did not exist. This would have been the case had Drs. Prince and Varian's cases been presented for trial. Beyond a doubt, ont hese points alone, they would have been ruled out of court.

Referring once more to the case of Dr. Jones, which has been so recently before the profession, she says, in answer to a letter of mine, that "she is glad to know that the subject of the medico-legal aspect of abdominal section is to come up for discussion at this meeting," and states as follows: "There is a necessity to look into these subjects. Under the existing laws of the State of New York a surgeon has no protection. If, in his efforts to relieve the sick and suffering, he decides to do abdominal section, or indeed to perform any surgical operation, and if, notwithstanding his best directed efforts, the patient should die, he is liable to, or may have, a suit for malpractice, or an indictment for manslaughter in the second degree. If the patient lives and does well, there may still be a suit for malpractice. The surgeon may spend his strength, his time, and give his best efforts to relieve the suffering poor, yet, under the law, and by the law, these same persons, for whom he has labored, may turn and rend him, and use every effort for his destruction, personal and professional. Malice at any time may so construe the law that at any unexpected moment the surgeon or physician may find himself in the most serious and unpleasant difficulties. Thus, it is simply dangerous to practice medicine and surgery in the State of New York. A distinguished lawyer said to me the other day, that however well prepared he might be, yet he would not, as the law at present stands, *dare* to practice medicine, and he thought he had about as much courage as most people.

"Section 200 of the Penal Code says:

'LIABILITY OF PHYSICIANS.

"'A physician or surgeon who, being in a state of intoxication, administers a poisonous drug or does any other act, as a physician or surgeon, to another person, which produces the death of the latter, is guilty of manslaughter in the second degree.'

"But according to Judge Barlett's ruling 'Physicians are also liable, under Section 193 of the Penal Code, in connection with the preceding provisions.' Subdivision 3 of Section 193 says: 'By any act of procurement or of culpable negligence.' This comprehends a great deal, and can be made to mean anything. A physician or surgeon, though he may have the best preparation, yet by any act of procurement as administration of medicine or surgical operation, if the patient dies, he may be found guilty of culpable negligence. There will always be found physicians who would have used different procedures, or advised another course as preferable.

"If a surgeon, for the welfare of a patient, deems it best for him or her to perform abdominal section, and death ensues, malice can, under Subdivision 3 of Section 193, have him indicted for manslaughter in the second degree.

"If a surgeon neglects to perform abdominal section, when, in the estimation of another, it should have been performed, and the patient dies in consequence of the pelvic conditions, that surgeon, under Subdivision 3 of Section 193 of Penal Code, can be found guilty of culpable neglect, and indicted for manslaughter in the second degree.

"Judge Bartlett says further: 'If a person assumes a certain amount of skill, and does not develop that amount of skill in his act, is guilty of culpable negligence.' How largely malice or blackmail may misjudge this skill and use the law for direct persecution, or, as the *New York Medical Journal* puts it, for "roasting physicians.'"

Notwithstanding the strong points she presents, I am of the opinion that the courts have ruled in justice to all concerned in these cases. It is necessary that the public have proper protection; that while we must advance in our profession only by experience and accumulated skill in the doing of untried operations, yet in their performance great caution and the careful study of cases becomes a necessity. It will be observed that while it has been a great hardship and required much resolution for the surgeons who have been attacked, to defend themselves, yet they have, in the end, triumphed.

What I would like to see as the result of this discussion is the betterment of our laws in this, that the surgeons may have better protection in the recovery for loss of time, for expenses they have been put to when it is proven that the case was urged by some disreputable lawyer, or by those personally malignant within or without the profession.

My conclusions then would be:

1. That we should exercise the greatest care in the examination of our cases of doubtful diagnosis.

2. That when in doubt we should lay great stress upon the necessity of an exploratory incision, and make a very proper explanation of what this means to the patient and friends.

3. That in the cases thus far brought to trial we have reason to believe that the judges, in their rulings, have treated our profession with great fairness, the strong points being that the public good is not subserved by undue and willful prosecution of the surgeon who has shown the proper amount of intelligence in his profession.

4. That we should seek still to have the law so made in our favor as to eliminate the cases of willful prosecution.

5. That in the careful study of these cases we have presented the lamentable condition of expert testimony. Men absolutely ignorant upon the subject, men who have never done an operation of any merit in surgery, being allowed to come upon the witness-stand and testify as experts.

ONE new case of cholera and one additional death therefrom are reported at Puebla de Rugat. There has also been one more death at Gaudia.

THERE is plenty of the milk of human kindness in Councils, but it doesn't always size up to the 12 per cent. standard when action on an inspection bill is required.

REPORT OF CASE OF CHOLECYSTOTOMY, WITH EXHIBITION OF SPECIMENS.[1]

By RUFUS B. HALL, M.D.,

Surgeon to the Cincinnati Free Hospital for Women; Professor of Gynecology at the Cincinnati Polyclinic; Clinical Lecturer on Gynecology at Miami Medical College; Fellow of the British Gynecological Society; Fellow of the American Association of Obstetricians and Gynecologists, and of the American Medical Association, etc.

MY purpose in reporting the following case is to illustrate how little is accomplished by nature's effort in some cases of obstruction in the common bile duct, and at the same time to emphasize the necessity of operative interference, as soon as it is evident that nature is not competent to overcome the obstruction. Mrs B., aged thirty-nine years, mother of seven children, the youngest six years of age. She is a slender woman, never weighing more than one hundred and fifteen pounds, and has always enjoyed fair health previous to the present illness.

February 6, 1890, she was seized with an attack of pain, and sent for the family physician—Dr. E. S. Stevens, of Cincinnati. He found her suffering with hepatic colic of a severe type. Hypodermic injections of morphine were given for the relief of pain. She vomited a number of times, and for three days the ejected fluid contained bile. The morphine was required for four or five days, when the pain subsided. About that time it was observed that she had slight jaundice, which remained about one week. It was now observed that there was an enlargement in the region of the gall-bladder; this enlargement disappeared in about two weeks. She was confined to her bed ten or twelve days. She had not regained her strength sufficiently to enable her to oversee her domestic duties when, on March 9, she had a recurrence of the pain, necessitating the use of morphine. The stomach became very irritable, and she vomited at short intervals; the fluid contained bile for four days. She was very much constipated during the entire illness.

March 19 it was again noticed that she was slightly jaundiced, which grew rapidly worse, until, at the end of a week, she was the color of a rusty, or dried-up, lemon. It was also noticed that there was again an enlargement in the region of the gall-bladder, the size of a closed hand. The stomach became exceedingly irritable; she vomited as often as every fifteen minutes, for hours together, and during her entire illness she rarely went four hours without vomiting. But after the jaundice became manifest in the second attack of pain, there was no *indication of bile*, either in the fluid vomited or the stools. Thus it was reasonable to infer that the obstruction was in the common bile duct, and, from the sudden onset of the symptoms, that the obstruction was due to an impacted gall-stone. The pain was not so severe now as in the commencement of the attack; a half grain of morphine, two or three times in twenty-four hours, made her condition bearable. Although she suffered great pain, she said "her greatest suffering was from the nausea and vomiting." Notwithstanding she had regular rectal nutrient enemeta, she suffered greatly from hunger, and said "that she could appreciate the feeling of shipwrecked sailors who were driven to that desperation from hunger that they killed and ate their companions."

About April 1 she was in a condition that an operation appeared to be the only means that could afford relief, and it was so stated to the family; but their consent to an operative interference could not be obtained. The following day her condition appeared to be better in every way. She remained better for a few days; yet she suffered so much from nausea and vomiting that she required morphine, which relieved the distressing symptoms to some extent. All the usual remedies for nausea and vomiting, including cocaine, phenacetine, and hydrocyanic acid, were tried, with only temporary relief.

April 11 the emaciation was extreme, her estimated weight was ninety pounds; the suffering from the pain and sick stomach was great, and it was evident that she would not live long unless she could be relieved. At that time her husband consented to a consultation with reference to an operation. I saw the case with Dr. Stevens, the 12th. She was in a dazed condition—listless, and did not appear to notice anything or any one about her; yet, she answered questions rationally when spoken to. Pulse, 100; temperature, 97½°; cholæmia, extreme. At that time the liver was enlarged; the lower border was easily defined about four inches below the ribs. It could not be determined, at the examination, that the gall-bladder was enlarged. She vomited a little glary mucus every few minutes. The patient appeared to be in a dying condition. She was so feeble that any operative interference seemed to promise nothing but a fatal termination; yet this promised a slight hope, and there appeared to be no hope if the case was left to nature. This statement was made to the husband and friends, and they quickly decided to have the operation made.

A patient in this condition has more than the ordinary dangers encountered in other abdominal operations. The deteriorated condition of the blood which had existed so long, and her extremely feeble and emaciated condition, made it very doubtful if she would be able to bear the operation and subsequent shock. Even if she passed through these, the great danger of secondary hemorrhage was yet to be encountered—which is one of the most dreaded and frequent complications following gall-bladder operations upon cholæmic subjects.

Greig Smith[1] says: "Cholæmia, not only as weakening and depressing the patient, but also predisposing to bleeding, is an unfavorable element. In only seven of Musser's and Keen's series of thirty-five cases of cholecystotomy was jaundice present, and five of these cases died—half of the whole mortality. That the jaundice had much to do with this excessive death-rate there can be no dispute. This suggests early operation, before the patient's condition is lowered by cholæmia."

In seventy-three cases quoted by Smith, where the gall-bladder was sutured to the abdominal wound, eleven died—five from hemorrhage and collapse. He says "collapse with hemorrhage would seem to be the most usual cause of death; and this cause is the most potent in cholæmic individuals." In this case it proved to be an exceedingly grave complication.

The operation was made April 13, 1890, at 10 A. M. An incision, two and one-half inches long, was made two inches to the right of the median line, over a prominence, which could be distinctly felt when the patient was under the anæsthetic. This prominence was supposed to be the gall-bladder. Upon opening the peritoneal cavity firm adhesions were encountered with omentum and intestine, and the enlargement that was supposed to be the gall-bladder proved

[1] Read by title, Ohio State Medical Society, June 4, 5, and 6, 1890.

[1] Third edition, pp. 600–601.

to be the edge of the liver. The gall-bladder was enlarged, but the lower end of the bladder was just at the upper end of the incision, which necessitated extending the incision upwards about two and one-half inches. After separating several coils of intestines, I could detect several stones in the enlarged gall-bladder, which was aspirated and six ounces of gall removed, which I expected to present to you, but it could not be preserved or kept in a condition to bring here. I then incised the gall-bladder and removed four gall-stones, which were lying loose in the bladder. In searching for the cause of the obstruction it was easily found, and proved to be a stone impacted in the common duct. With the fingers upon the duct, over the stone, it was removed without much difficulty. The stones here presented are those removed; the sharp-pointed one is the one that was impacted in the duct. After passing a probe into the common duct and detecting no more stones, the gall-bladder was stitched to the upper end of the abdominal incision with interrupted sutures, and the remaining two inches of the abdominal wound closed in the ordinary way. As there had been quite extensive and firm adhesions to separate, I placed a glass drainage-tube in the abdominal cavity. A rubber drainage-tube was placed in the gall-bladder. There was very free bleeding from the edges of the abdominal wound and wound in the gall-bladder during the operation.

After the completion of the operation we placed the patient in bed, with no hope that she would ever rally. She regained consciousness very slowly. At 4 P. M., five hours after the operation, her pulse was 124; temperature, 99°; patient semi-conscious; dressing stained with blood and half ounce of blood removed from the abdominal drainage-tube; there was oozing of blood between all of the stitches. I then gave directions to the nurse that the drainage-tube should be pumped out every half-hour, and the wound carefully watched in reference to the bleeding, that we might make an intelligent estimate of how much blood was lost in a given time. Each inspection revealed increasing hemorrhage; so, by the following day at 11 A. M. she was losing blood at the rate of two ounces every three hours. The loss of this amount of blood from one so feeble gave us no little anxiety, and the fact that it was increasing in quantity from hour to hour, instead of decreasing—as we naturally hoped—made the prognosis more grave still.

At 5.15 P. M. Monday, thirty hours after the completion of the first operation, the patient was bleeding as freely as at any time since the hemorrhage commenced. She was semi-conscious; pulse, 124, and very feeble; temperature, 98°. The blood came from between the stitches at the lower end of the wound below the gall-bladder, and from the abdominal drainage-tube. I could not tell whether the bleeding came from a point within the abdominal cavity, or from the edges of the abdominal incision. It was plainly evident that the patient could not long survive if the bleeding could not be controlled. After a short conference with her husband I gained his consent to again open the abdominal cavity to search for the bleeding point. I was very anxious not to disturb the stitches which attached the gall bladder to the abdominal wall, as there did not appear to be much bleeding from that part of the wound (only a little oozing between the stitches).

With the assistance of Dr. Stevens and Mr. Rice, a student in medicine, the patient was given an anæsthetic upon the bed, and the stitches removed from that portion of the abdominal wound below the gall-bladder. There was free bleeding from every portion of the edges of the wound. Around the glass drainage-tube in the cavity was considerable blood-clot—perhaps two ounces. After sponging this out, I soon satisfied myself that the bleeding all came from the wound in the abdominal wall, and a part of it entered the cavity outside of the tube and was removed with the pump through it. After this fact was determined I at once removed the glass drainage-tube and closed the cavity by uniting the peritoneum only with a continuous suture of catgut. When this was accomplished I proceeded to close the rest of the wound in the following manner:

With a Hagerdorne needle upon each end of a thread I passed one needle from within outward, including the whole thickness of the abdominal wall except the peritoneum, including a large bite of tissue, the needle coming out about one inch from the edge of the incision. The needle on the remaining end was passed in like manner on the opposite side; all the stitches were placed in the same manner, and about one-fourth of an inch apart; they were tied very tightly, thus making firm pressure upon the edges of the abdominal incision. This practically controlled the hemorrhage, yet the wound continued to bleed between all of the stitches for eight days longer, but not more than two or three drachms a a day.

The patient went through the second operation fully as well as the first. For fully a week her temperature was subnormal one or more times during each twenty-four hours. The highest point reached was 99.4° except once, when it reached 100°. There was a free and constant flow of bile from the drainage-tube in the gall-bladder for eight or ten days, when it became intermittent. The tube was removed on the sixteenth day, and on the twenty-first day the sinus was closed. The cholæmia rapidly disappeared; a marked improvement could be observed on the third day after the operation. She complained of nausea but little after the third day, and vomited but twice after the operation was made. On the third day she retained liquid food, and after the fifth day she had a ravenous appetite.

The stools showed the presence of the bile from the first movement, which was on the fourth day.

On the twenty-eighth day she was able to go down stairs, and is now rapidly regaining her strength.

To summarize: The following special points can be emphasized in this case:

1. The complete success of surgical interference in the almost hopeless condition of the patient.

2. The perfect success of the use of compression by means of very deep and firmly-tied sutures.

And here I may remark that had this failed to check the bleeding I would have cauterized the bleeding surface down to the peritoneum, dressing it as an open wound.

154 West Eighth Street.

The Guild of the Iron Cross, of St. Clement's church, has been, for several weeks past, taking parties of working boys into the country on Saturday afternoons. They are provided with food, suitable games, and, what is regarded as more important, a half-holiday in the fresh air. Tickets can be had on Tuesday and Friday evenings at the Iron Cross office, 2021 Cherry street, from 7 to 8 o'clock. Help is needed to carry on this work, and any contributions sent to the Rev. Father Field will be thankfully received.

THE RELATIONSHIP OF SOMNAMBULISM TO EPILEPTOID AND EPILEPSIA. —A NOTE.

By C. H. HUGHES, M.D.,

Former Superintendent of the Missouri State Lunatic Asylum; Professor of Psychiatry and Neurologia, Marion-Sims College of Medicine, St. Louis.

THE TIMES AND REGISTER, referring to an article of mine on the Alternative Psychoses of Epilepsia, notes some of the somnambuliform automatisms there recorded as occurring in undoubted epileptics as supplemental and substitutive of the ordinary epileptic seizures, and makes the suggestive and clinically warranted comment: "If this be epilepsy, the possibility of the same affection underlying cases supposed to be simply somnambulism should be considered."

Undoubtedly! Somnambulism is a morbid state of the brain, a nocturnal cerebral vascular psychosis closely allied to epileptoid. I think it has been allied to epilepsia by other observers than myself. It involves the psycho-motor area of the brain as epilepsia does, and has its exact counterpart in many of the automatic alternative states of epileptic disease. I have been for many years so thoroughly satisfied of this fact that I have treated and broken up the habit in a number of instances, in a manner similar to the management of a case of epilepsia mitior, and have invariably, of late years especially, advised treatment of all somnambulists.

Clinical records show somnambulism, hysteria, dipsomania, and epileptoid states, as well as the pronounced insanities, as alternative conditions in neuropathic family histories; the children of somnambulists, hysterics, and inebriates are often found to be epileptic as well as insane, and *vice versa;* though we more often find the descendants of somnambulists and mild hysterics to have the lighter nervous troubles, as chorea, migraine or neuralgia.

I have personally known many instances where somnambulism has taken the place of hysteria and epilepsia in neurotic families, and several where a somnambulic father or mother has borne an epileptic child; and several instances where I suspected epileptics to have been the product of a coitus in which father or mother was in the trance state of inebriety, or the automatic mental state that sometimes follows or supplements an epileptic fit; but not until during the past week have I seen an epilepsia in a child traceable to unconscious copulation on the part of the father while in the nocturnal automatism of the somnambulistic state. This man was so profoundly unconscious in his somnambulism that, on one occasion, he broke a window with his fist, to jump out, without being awakened till his wife dashed water on him and did some other things to arouse him.

The father seemed to think that, because his wife's conception dated from one of his unconscious somnambulistic periods, that this was the all-sufficient explanation of his child's epilepsia. The child's mother died of phthisis, and never had hysteria, epilepsia, or other marked neurotic trouble.

You have seen proper, in your issue of May 24, to refer to the case of a boy reported elsewhere by me, who "completely undressed himself, crying as if in fright, and then replaced his clothing; no convulsive act following or preceding. He would struggle till the fit was over if interfered with." And to another, who "arose one night at the time of the fit, dressed himself, walked to his barn and pasture, looked several times at his watch, returned, undressed methodically, and went to bed; from which he arose next morning, unconscious of the occurrence."

This note is a brief exposé of my views on this clinically important subject, a subject always as interesting to the neurologist as syphilis in its protean forms is to all physicians. It is another view of the many-sided neuropathic diathesis, or instable nervous constitution. A volume might be written upon the subject as entertaining, in fact, as an entrancing novel.

Jules Verne's fictions "Under the Sea" have lately been almost verified in the Coubert torpedo-boat of French science, the phonograph, graphophone, etc.; but the marvels of the nervous system revealed in the psychopathies and neuropathies transcend even the flight of fancy.

As I write, in verification, I have just finished examining a bright little boy of five years, who has lately been stricken with a peculiar form of aphasia, without fever, rheumatism or paralysis, who can only recall the wanted words by mental circumlocution and rubbing the hand forcibly for some seconds against a hard substance, or the opposite hand, or the wall, or a table.

The above is a brief answer to your conjecture based on my cases, viz.: that epilepsia and somnambulism are often the psychical or psycho-motor wave that follows the subsided epileptic storm in the individual, or it may be the swell that follows the neuropathic storm in a preceding generation, or it may presage a neuropathic hurricane later on in the family descent. It is always more or less a neuropathic disorder, as the night terrors of children and the morbid fears of neurasthenia and all forms of neuratrophia are, and as such demands therapeutic attention and more medical consideration than has been given to it.

There are more things in epilepsia and epileptoid states than have been dreamt of in our clinical philosophy.

500 NORTH JEFFERSON AVE.

Society Notes.

OHIO STATE MEDICAL SOCIETY.

Forty-fifth Annual Session, at Columbus, June 4, 5 and 6, 1890.

President, DR. J. MCCURDY, of Youngstown, and Secretary, DR. G. A. COLLAMORE, of Toledo.

THE secretary reported a membership of five hundred and thirty-six, and nine deaths during the year. The following officers were elected for the ensuing year: *President*, Dr. W. J. Conklin, of Dayton. *Vice-Presidents*, 1st, Dr. D. N. Kinsman, of Columbus; 2d, Dr. B. L. Millikin, of Cleveland; 3d, Dr. D. J. Snyder, of Scioto; 4th, Dr. Orpheus Evarts, of College Hill. *Secretary*, G. A. Collamore, Toledo. *Assistant Secretary*, Dr. J. A. Spence, New Philadelphia. Next place of meeting, Put-in Bay, June 17, 1891.

Papers were read by Dr. C. F. Clark, of Columbus, Errors of Refraction and Muscular Adjustment as Causes of Nervous Phenomena; B. L. Millikin, Cleveland, Cleanliness in Eye Surgery; Dr. N. P. Dandridge, Cincinnati, Surgery of the Knee Joint; Dr. D. P. Allen, of Cleveland, showed a woman on whom he had done a successful nephrectomy.

A committee appointed to secure the more thorough organization of the State, reported in favor of making the members of all the county societies members of the State society, as is done in Indiana. The recom-

mendation was taken under consideration for one year, and the committee continued.

Dr. N. Senn, of Milwaukee, on motion of Dr. R. Harvey Reed, of Mansfield, was elected an honorary member of the society.

TREATMENT OF COMPOUND COMMINUTED FRACTURE

was the subject of a paper by Dr. S. L. McCurdy, of Dennison. The doctor exhibited a number of specimens, mostly of railroad injuries. He was a young man, and advocated heroic surgery, saying conservatism was an excuse for ignorance and cowardice.

The Role of the Microbe was the subject of a wise paper by Dr. A. R. Smart, of Toledo. The Aetiology and Treatment of Pheumonia was the subject treated of by Dr. S. P. Deahofe, of Potsdam, and Vaginal Hysterectomy, by Dr. A. B. Carpenter, of Cleveland.

CARCINOMATA MAMMÆ

was the subject of a paper by Dr. Dudley P. Allen, of Cleveland. The doctor believed the common rules for diagnosis and the prevailing advice as to the operation were bad. He insisted very strongly on the early operation. He thought we should not wait for immobility of axillary glands, or for infiltration of tissues and depression of nipple. He recommended as a method of gaining access to the axillary space, the finding of the axillary vein, and following it up. On early diagnosis and operation depends the success of the case.

Dr. W. W. Pennel, of Fredericktown, used chloroform in the first, second and third stages of labor. He thinks accidents are due to carelessness. In nine-tenths of the deaths from chloroform, the fact of the matter is that the chloroformist does not attend to his business.

PUERPERAL FEVER

was the subject treated by Dr. G. H. Colville, of Harrisville. He favored antiseptic precaution and time in the open air, after having seen an infectious case, before going to a woman in confinement.

Dr. D. N. Kinsman, of Columbus, did not believe in auto-innoculation, or that the disease was carried by scarlet fever. He believes that the poison is introduced through some abraded surface in the genital organs, through which it gains access to the blood. He advised thorough antiseptic treatment of the genitals. Cases formerly regarded as hopeless, under modern ideas of antisepsis, are cured.

THE HIGH AMPUTATION OF THE CERVIX *vs.* TOTAL EXTIRPATION OF THE CERVIX

was the subject treated of by Dr. T. A. Reamy, of Cincinnati. He argued that if we remove the whole uterus for epithelioma of the cervix, why not remove the vagina, bladder and fimbriated extremities of the Fallopian tubes? Three cases in New York, post-mortem, showed disease limited to the external os. Two cases in this section of the country, pathologist showed were not subjects of cancer at all. Women are victims of the rage to mutilate women.

The President's address, by Dr. J. McCurdy, Youngstown, was on the subject,

THE CARE AND TREATMENT OF THE INSANE IN THIS COUNTRY.

He compared the history of the treatment of the insane in the various countries with that in the United States, which was to the great credit of the latter country. The Friends of Philadelphia were the first to treat the insane kindly. He advised the taking of the incurable cases from the county poor-houses and placing them in specially-adapted institutions. He thought the law of New York State should be followed by others, viz., that all officers and attendants should be compelled to pass an examination, and not allowed to enter upon the work unless qualified. They should, when fully entered upon their duties, be placed upon the civil list, and not subject to the caprices of politics. The asylums should be built on the cottage plan. One-half acre should be allowed to each inmate, and rural life encouraged. Medical societies should recognize more than they have done the study and treatment of the insane.

THE RECENT EPIDEMICS OF DIPHTHERIA, SCARLET FEVER, AND LA GRIPPE AT THE SAILORS' AND SOLDIERS' ORPHANS' HOME AT XENIA

was the subject of a paper by Dr. C. M. Galloway, of Xenia. He thought the pages of history might be searched in vain for instances where the attendants in public institutions did more, better, and more faithful work in epidemics of contagious diseases. The Home contained about 1,000 children, and the history of the rise and progress of the disease, and the tireless efforts to dispel it, was truly interesting. Children were placed in certain cottages as often as three times, and still the epidemic returned. It was finally necessary to tear out the floors and plumbing. One young lady of Xenia volunteered to attend the little sufferers, and died of diphtheria. The disease could have been better handled had the hospital accommodations been greater.

THE MORE FREQUENT USE OF CHLOROFORM IN OBSTETRICS

was the subject of a paper by Dr. J. F. Baldwin, of Columbus. His conclusions were as follows: Chloroform relieves pain; it shortens labor; it prevents shock; it prevents nervous and physical exhaustion; it reduces the liability to rupture of the cervix and perineum; it does not conduce, to any material degree, to post-partum hemorrhage; it does not affect the fœtus; it is absolutely safe when properly administered.

He knew of no real contra-indications to its use, and urged that the boon be given to all women who asked it. He uses it chiefly in the second stage, carrying anæsthesia to the obstetrical degree merely; but at the last moment, when the head is distending the vulva, and the agony is most extreme, he produces full anæsthesia. He spoke of the absurdity of the physician who, in the very acmé of human suffering, would refuse the blessed unconsciousness that he quickly supplies for the mere drawing of a tooth or lancing of an abscess.

THE FIRST PORRO OPERATION MADE IN OHIO

was the subject of a report made by Dr. J. F. Baldwin, of Columbus. The patient was a dwarf, twenty-four years old; forty-seven and five-tenths inches in height, with an antero-posterior pelvic diameter of one and one-quarter inches. The operation was successful, both mother and child being saved. He also briefly reported three laparotomies made by him during the year for various diseased conditions. Two of the operations were very difficult; but all the patients made excellent recoveries.

INTRA-PELVIC SURGERY FOR THE RELIEF OF INFLAMMATORY DISEASES

was the subject of a paper by Dr. R. B. Hall, of Cincinnati. This paper was a report of one year's work, and a supplement to ten consecutive cases of abdominal section for the removal of the uterine appendages. The cases tabulated reached eighteen

in number, and all but three had pus. All recovered. He wished to say that he could not make this report unmarred by a death, but that he had them where he could give them careful after-treatment. It has been asserted that the after-treatment in these cases amounts to nothing. As a rule they do not require long treatment, but need very careful attention for a few days at first. These operations are among the most trying in pelvic surgery. No exact estimate can be made before opening the abdomen of gravity and extent of the complications to be met with in any given case. No man has a right to open the abdomen unless he is prepared for any emergency which might occur, and is competent to deal with the conditions found on the spur of the moment. He thought that all cases of prolonged chronic salpingitis should have a prolonged and systematic course of treatment. In many of the cases reported it was impossible to separate the adhesions without bursting the pus sac. In every case where this occurred, and in those where there was much bleeding, the abdominal cavity was washed out. Free washing-out of the abdominal cavity need not be feared; the heat relieves the shock. He has constantly employed it, when necessary, for three years, and has not seen a single case where it caused bad symptoms. The irrigation is continued till the water returns clear. Although all the cases recovered, many of them would not submit to an operation till *in extremis*. The doctor had seen four cases in consultation and advised an operation, which was refused by the physicians in charge and the friends of the patients because an operation involved danger to life. All of these cases died within a few weeks from peritonitis, with every indication of ruptured pus tubes. Three of these cases were proven by autopsy. There is danger in the so called conservative or let alone plan in cases where there is pus in the pelvis as well as in operation.

The Polyclinic.

PHILADELPHIA HOSPITAL.

HÆMOPTYSIS.

I HAVE two cases to present that had the same symptoms in common, and that is hemorrhage from the lung. Neither one has bled profusely except the one who lost a considerable amount of blood at one time and has bled several times since. The first patient has a fair family history; neither parent had phthisis, but one brother died with it. This man has always been well. His occupation has been that of a driver, and by reason of this he has been exposed to all kinds of weather. In 1888 he injured his back by a fall, in the summer, and was treated five months. Since then he has suffered with a weakness in the region of his back. In January, 1890, he had an attack of influenza, and in three weeks he resumed his work. Soon after he was exposed to rain, took cold, and was laid up for three weeks. He has not been well since that time. Cough has persisted, night sweats, and has lost flesh. He had an attack of hæmoptysis, and the next day lost several ounces more blood. He coughs, but raises no sputum. When this history was taken, the cause of the cough was due to pleurisy of the left side. In February he was tapped, and two or three ounces of pleural effusion were removed. A second tapping was done, and, since then, while he has improved some, he has not improved in strength.

Hemorrhage from the lung is due to many causes. It is associated with heart trouble, and, next to this, tuberculosis. Mitral obstruction is the most frequent cause of hemorrhage from the lung. Besides these causes, we have small aneurisms of the aorta that may rupture into the bronchi or trachea; but it is easily diagnosed. There is also a simple bronchial effusion that is associated with whooping-cough and bronchitis, with slight staining of the expectoration.

When there is no tubercular trouble, hemorrhage from the bronchial tubes is a small affair. Where there is a decided hæmoptysis, you may take it for granted it does not come from bronchial oozing, but to an ulcerative process—excluding heart-trouble—and we must consider it to be due to tuberculosis. Some say it is due to nervous excitation, just as in blushing or flush of the face. Virchow gives many instances of hemorrhage of the lung due to a modified circulation, owing to nervous influences, without any lesion of the heart. Such conditions must be very rare; for it is known that, in the most intense engorgement of the lung, in pneumonia, we do not have any true hemorrhage, but only a blood-stained sputum. I think, therefore, in spite of high authorities, I would hesitate to attribute hæmoptysis simply to nervous causes.

This man has had several hemorrhages from the apex of the right lung, where there is a prolonged respiratory murmur and adventitious, moist rales. There is no respiratory murmur over a considerable part of the lower lobe of the right lung, which means a pleuritic effusion. I think this man has tuberculosis. From the fact that pleurisy so often coëxists with tuberculosis, some authors go so far as to say that pleuritic effusion means a tubercular process. I do not believe in this one-sided classification of pleurisy as tubercular in origin; but, in many instances, this is the case—such is the case in this man. I do not think there is any question but that this hæmoptysis is due to ulceration, caused by irritation of the bacillus tuberculosis, with erosion of the blood-vessels.

In most cases, hemorrhage does not require any treatment, but absolute quiet and rest, as a clot will form in the orifice of the vessel and check the hemorrhage. Keep the heart quiet; and, to do this, you may have to use aconite, veratrum, or the bromides. I think the most important point is for the physician to be self-collected and quiet, and not to show any alarm, and not allow the patient to get alarmed. Place the patient in a horizontal position, and, if he cannot quiet himself, give opium. Some say opium acts as a hæmostatic; but I do not believe it has any other effect than quieting the respiratory act—lessening the frequency of the respiration. If the hemorrhage is profuse, give decided doses of opium before ergot. If hemorrhage is bad, give hypodermics of ergot, and apply ice over the seat of the hemorrhage, if it can be found—usually over the apex. At the same time you may place the ice over the heart, as it quiets it. Besides this, we have the method of inhalation of styptic sprays; but this is almost impossible, for enough cannot be inhaled to reach the seat of hemorrhage; and, again, I think that the deep inspirations rather induce than lessen the hemorrhage. If you do use inhalations, use a light turpentine, that is very volatile. Keep the patient at rest a considerable time and improve nutrition.

How long should a patient recovering from an attack of hæmoptysis be kept in bed? It is not easy to decide how long to keep him there. You do not want to confine him longer than is necessary. If

there is any fever present, he should not get out of bed. This point should be first, and when, in your judgment you think it safe, allow the patient to get up.

The other case is similar to this one, and what is good for the one will apply to the other as well.

—*Walker.*

Dr. Clara Marshall recommends the following as a very valuable application to the vagina:

℞.—Acidi carbolici	gtt. xxxij
Alum	ʒ iv
Sodii borat	ʒ ij
Potassæ	ʒ j
Morphinæ sulph.	gr. vj
Olei olivæ	ʒ ij—M.

Inflammatory Leucocytosis.—Von Limbeck's investigations, brought forward at the Heidelberg Congress last year, have shown that the white corpuscles of the blood, physiologically increased in number during digestion, are considerably increased in number in all acute diseases which are accompanied by coagulating exudations—for example, lobar pneumonia and suppurative peritonitis. This increase does not occur in the infectious diseases which give rise to no exudations into the tissues—for example, typhoid fever, intermittent fever, septic fever, even if the temperature rises very high. The danger of this inflammatory leucocytosis is mostly proportioned to the degree of exudation and its richness in cells; it declines critically with defervescence; it does not occur with stationary exudations, and it is not diagnostically, but prognostically, a valuable criterion. In a discussion on this subject, at Prague, von Jacksch confirmed the statements of von Limbeck as regards typhoid and lobar pneumonia in children, the proportion of white to red corpuscles being 1 : 40 to 75. In the latter disease, the hæmoglobin amount was also distinctly lessened.—*British Medical Journal.*

If taken early, the treatment of acne vulgaris is unattended with any difficulty. It is quite a different matter when the case is neglected, as in this instance, or improperly treated.

Miss E. was ordered a bland unstimulating diet, and, twice a week, the following pills at bedtime, followed by a wineglassful of Hunyadi Janos water in the morning:

℞.—Pil. hidrarg.	gr. iij.
Pil. rhei co.	gr. vij.

Ft. pil., ij. Also:

℞.—Acid nitro hydroch. dll.	ʒij.
Tinct. cinch. co.	℥ij.
Infus. cascarillæ ad.	ʒviij.

Ft. mist. sp. coch. amp. ter. die.

Morning and evening the patient was directed to bathe the face with warm water as hot as could be borne, and the following ointment afterwards applied:

℞.—Iodid. sulphur.	gr. x.
Lanolin	ʒj.

Ft. unguent.

Each pustule was touched with the acid nitrate of mercury, twice a week.

This treatment was steadily persevered in, and on the 23d December, 1889—about three months—the nodules and all signs of the disease had entirely disappeared.

I would point out the great value of iodide of sulphur as a local application. The strength should never exceed ten grains to the ounce in the first instance, and perseverance in its use will certainly be rewarded by the ultimate cure of one's patient.

—Hillis, *Med. Press.*

Phenacetine in Whooping-Cough and Bronchitis.—If there is any remedy which will control a disease in a few days, which, if left to run its natural course, would last an average of ten weeks, it may be safely said that in one disease, at least, science has accomplished something. Who has not felt, as he has seen the victim of whooping-cough struggling in its convulsive paroxysms, with its face purple, its eyes bloodshot, and its hands wildly thrown about in agony, the poverty of his art and his science for any relief it could bring to his patient. Scores of remedies have been introduced as specifics, and yet none have been more than partially successful. Possibly the new remedy, phenacetine, may share the fate of its predecessors, and yet we have seen such wonderful results from it in the catarrhal and spasmodic stages of whooping cough, in the teasing and spasmodic coughs of bronchitis and laryngitis, we are led to hope that in this class of troubles it will yet rival quinine in its own specific field.

In a typical case of whooping-cough in a child eight months old, which had passed through its catarrhal stage and was well on in the second or convulsive stage, the paroxysm coming on every hour of a violent character, the action of the drug was almost magical. Under the influence of grain and a half doses every three hours, the paroxysms, in three or four days, were reduced to half a dozen light ones during the twenty-four hours, and in a week had entirely disappeared. Another case was when the attack had not fairly entered the second stage, and yet the exposure of the child and the peculiarity of the symptom left no doubt as to the character of the disease. In three days the cough had very nearly disappeared under the influence of two-grain doses of the drug every four hours, and in a week's time he was able to return to school. In the schoolmate from whom the disease was contracted, the disease was two months in running its course. In both of these cases the vomiting speedily ceased and the appetite returned. Many other cases occur to us as we write, but the ones quoted above were typical, and will suffice to illustrate the prompt action of the remedy. A lady of middle age was attacked with a sharp pharyngitis, the inflammation, as it was relieved in the pharynx, extending down and involving the larynx and upper bronchial tubes. The expectoration was bloody and purulent, and the cough frequent and painful. In addition to the usual medication five-grain doses of phenacetine was given at first every three hours, and as the cough subsided, every four or six hours. The effect was immediate; with the first dose the whole nervous system was quieted, the cough became less frequent, the temperature diminished, and in a few hours the patient fell into a quiet sleep. The improvement was rapid. There is no doubt the drug produces a very marked effect in relieving the irritability of the nervous system, and acting specially upon the vaso-motor nerves, controls to a certain extent the circulation without any dangerously depressing action upon the heart. As an intercurrent remedy we have reason to believe that in many cases it will supersede opium and its alkaloids, and the class of hypnotics of which chloral is the type, because it not only does not prevent, but aids by its quieting power the specific action of other drugs. We have been particularly pleased with the action of phenacetine in the epidemic of grippe, through which we have just passed. In connection with other indicated remedies it has been in our hands of very great service.—*N. Y. Medical Times.*

DYSENTERY.

DYSENTERY is one of the old-fashioned diseases, concerning the treatment of which we should have had our minds made up some centuries ago. But if there is any single fact, theory or hypothesis in the practice of medicine upon which the entire profession agrees, the writer would be humbly thankful to be informed what it is. Simple inflammations have been long considered common ground on which comparative harmony is to be looked for. But since croup is now coming to be considered diphtheritic, and pneumonia is of bacillar origin, we have become unsettled as to what is a simple inflammation, or whether such a thing exists.

In that halcyon period of which we now dimly perceive the first streaks of the dawn, every symptom and sensation, perhaps every emotion, will be instantly recognized as attributable to a bacterial invader or an autogenetic poison. "That tired feeling," which the nostrum-vender sagaciously presupposes as existent in 99 9 per cent. of his fellow-citizens, will be at once traced to the micrococcus lazygenatus, or to the ptomaines generated by overwork and underfeeding. But, as yet, we are existing in the chaotic stage, when nobody knows anything sufficiently to enable him to convince his neighbor of his knowledge.

In that exponent of the *Age* which flourishes in Alabama, and worthily represents the medical art as there practised, Dr. Arbery gives an interesting chapter of personal experience with dysentery. He started in professional work with the conviction that the only proper treatment of this disease in any form was the administration of ipecacuanha in doses of forty grains every twelve hours. This was enforced upon him at his college by the general belief that any other method of treatment suggested would deprive the candidate of the Professor of Practice's vote for graduation. But, when our young doctor's first case of dysentery applied to him and he used the ipecac, the patient objected so vigorously to its harsh action that this method was given up for the future. The reasons for divergence in the views of fallible and not always profound or judicial minds may be seen in the possibilities opening out here for discussion.

1. The Professor may have been mistaken. A conscientious reader rather than a clinician, he may have been misled by the graphic accounts of this treatment in the grave dysenteries of the tropics, and concluded that the method was equally necessary and applicable here.

2. The tyro may not have had the practical skill of his teacher in using the drug. Large doses of ipecac are not likely to occasion much nausea if they are taken with barely enough water to wet the powder, and the patient lies perfectly quiet for some time after taking the dose.

3. The case may have been a very simple one, in which such heroic treatment was out of place. Youngsters are quite prone to the use of sledge-hammers, with which to drive the tacks that present themselves.

4. The patient may have had an idiosyncrasy towards ipecac; which gives rise probably to more idiosyncrasies than all the other drugs in the materia medica put together.

5. The drug may have been bad.

This list by no means finishes the sum of possibilities; but it is enough for illustration.

Looking further, for a less drastic style of medication, Dr. Arbery settled down upon the use of laxatives with opium for the milder cases. When this fails, he very judiciously compels his patient to go to bed and stay there until he is well. In any but very mild cases, rest is the first requisite of successful treatment. Dysentery imposes this necessity upon the patient, and he has for the time but one "business" to attend to: that of getting well. If relief does not quickly follow, Dr. Arbery resorts to his sheet-anchor: cold water enemas. He prefers copious ice-water flushings of the lower bowel, and says they are "grateful, pleasing, and comfortable to the patient," as well as salutary. Sometimes he adds the permanganate of potassium, and employs a retro-injection rectal tube, to keep up a continuous flow. This is followed by an enema of starch, with a full dose of laudanum. After the acute symptoms pass, if the bowels continue to act too frequently, he gives astringents.

It would be difficult to improve on this simple method of treatment in such forms of dysentery as are met with in this country. Many physicians prefer the use of hot-water enemas; just as many prefer hot poultices to cold compresses for pneumonia; but it is certain that in both instances the uses of heat and cold are so nearly alike that, in any given case, the choice may be guided by the sensations of the patient. Various substances have been employed in the thermal enemas, such as laudanum, flaxseed, starch, nitrate of silver, antiseptics; but we have never been able to satisfy ourselves that they added any efficacy. Heat and cold are agents whose inestimable power for good is apt to be overlooked when other agents are administered at the same time.

DYSENTERY is prevailing in several sections of Norristown, and the Board of Health will take prompt action for removing the cause. A large majority of the cases are in families who use water from private wells, which, it is believed, have become polluted by drainage from outhouse pits.

Annotations.

BARNES suggests that all ovaries removed should be preserved, classified and described, in order that the relations of these organs to mental affections may be studied. He mentions a collection made by Coste, of organs taken from women who had committed suicide, but which was scattered and the specimens spoiled, the custodians not realizing its importance.

A CURIOUS use of salol as a diagnostic agent is made by Pal, of Vienna. Acid compounds of phenol are broken up by the secretions of the pancreas and of any other part of the intestinal canal, except the stomach. If, then, salol be given, and the urine responds to the tests for salicylic acid, the salol has passed the pyloric orifice. In two cases where this reaction was not given, occlusion of the pylorus was diagnosed; and this was confirmed by the autopsies.

CREMATION.

THE cholera in Puebla de Rugat, Spain, proves to have originated from the opening up of an old cemetery in which the victims of the epidemic of 1885 had been interred. A few more instances of this kind will help along the cause of cremation. Just what good it does anybody to bury the body of a person dead of a pestilential disease is difficult to comprehend; and if five years' burial is not enough to destroy the specific germs, it becomes a question as to how long such a body continues to be a source of public danger. In the case of a remarkable outbreak of cholera in London, that was traced to the use of water from a certain well, it was shown that this well communicated with the great "gulf" described by Defoe in which were buried the bodies of those who died of the great plague in the time of Charles II. Possibly, cholera may have been an unnoted participant in that visitation, the tremendous mortality of the true plague blinding the public as to the co-existence of another malady; just as the eruptive fevers were long looked upon as varieties of the same disease, as they appeared in Europe at the same time.

If a body retain its infectious properties for prolonged periods, and perhaps infects the surrounding earth, as does the buried body of an animal dead of anthrax, cremation, in such cases, is removed from the domain of argument and becomes an unquestionable duty.

Letters to the Editor.

THE GIN COCKTAIL.

ACCEPT my thanks for your kindness and courtesy in directing my attention to a paragraph in your issue of June 14. The item is a gross perversion of what I said, and is as follows: "The gin cocktail is known to have certain gladsome and refreshing qualities in those milder states of asthenia which follow a day's work and precede an evening meal. Dr. George T. Maxwell, of Fla., however, in addition, recommends the gin cocktail as closely approaching a specific in yellow fever."

In the *N. Y. Medical Journal*, April 26, 1890, is a letter of mine on "The Treatment of Yellow Fever." My purpose and the purport of my letter were to emphasize the valuable suggestions of Dr. Guiteras and Dr. Faget, against the free use of medicines with curative intent. The second paragraph of my letter was as follows:

"Dr. Guiteras said: 'Without attempting to discuss the theories of treatment advanced by Dr. Faget, in another portion of this publication (Annual Report of Supervising Surgeon General, 1889), I find very little to add to the valuable instructions there given. . . . The truth is that, in the majority of cases, there is no indication for treatment in the first days of the disease.' And Dr. Faget said: 'The general plan of treatment, in my opinion, should be: make your patient comfortable.'"

Then, to show coincidence of view between those distinguished gentlemen and myself, I quoted from an article I published in the *Charleston Med. Jour.*, July, 1874, as follows: "Active treatment of yellow fever is worse than useless—it is hurtful. Drugs have no influence upon the disease to avert, or cure it. When I was sick with the disease, in 1853, I would not take a dose of medicine. . . . Were I called upon to give what I consider to be the best plan of treatment of yellow fever, I could do it in a word, viz.: nursing, good nursing—that is, make your patient comfortable."

"I rely entirely, so far as medical treatment—as distinguished from nursing, which comprehends baths, injections, food, ventilation, etc.—is concerned, upon morphine during the first days, gentle saline aperients when necessary, and gin cocktails when the pulse begins to falter. I suppose I must have given a half barrel of the latter in 1888."

This is all I have ever published on that subject, and you will agree with me, doubtless, that only malice, or stupidity, could have perverted what I said into "recommends the gin cocktail as closely approaching a specific in yellow fever."

Your item is credited to the *Weekly Medical Review*. I believe that the *N. Y. Medical Record* is entitled to the questionable honor of having invented the slander.

GEO. TROUP MAXWELL.

JACKSONVILLE, FLA.

Book Reviews.

PHILOSOPHY IN HOMŒOPATHY. By CHARLES S. MACK, M.D., Chicago: Gross & Delbridge, 1890; pp. 174, cloth, 12 mo.

A collection of short papers, written with the idea of obtaining analogies which will harmonize the homœopathic principle with accepted truths.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. Vol. 6, No. 3. June 1890.

Contents: Bronchial Asthma; Its Causes, Pathology, and Treatment. By John C. Horowgood, M.D., F.R.C.P.

Convulsive Seizures. By J. Hughlings Jackson, M.D., F. R. C. B.

Surgical Treatment of Diseases of the Brain. By Ernest Von Bergmann, Berlin. Index for Vol. VI.

DISEASES OF THE EYE. NOYES. Wm. Wood & Co., New York City, 1890.

In 1881 Dr. Noyes issued in Wood's Library of Standard Medical Authors a very creditable treatise on diseases of the eye. But since that time so many new and more voluminous books upon the subject have appeared, containing much later studies and ideas, that it was naturally incumbent upon Dr. Noyes to bring out a new book or edition of his former one, and to make it not only thoroughly up to the time in the general as well as special knowledge in ophthal-

mology, but to surpass all other single text-books in size, which latter he has succeeded most excellently by the thickness and quality of the paper used. His first book was a good one, but this is a very much better one in every respect. As he says, the spirit of the book is clinical, and in accordance with this practical intent he has omitted mathematical formulæ, which are so confusing for the general reader, belonging only to the domain of the specialist. He gives all that is necessary in pathology and microscopic anatomy for the well understanding of his subjects and processes, especially in the combination of the eye with the other parts of the system, as brain, kidneys, etc.

The whole book is well illustrated, and written in a plain, readable, and readily understood manner, making it one of the finest text-books upon the subject lately issued. He follows the well known line of Stellwag in presenting the divisions of his subjects of diseases in the causes, the symptoms, the course, the prognosis, and the treatment, in a concise, clear manner, so that every part is clearly defined and readily understood by the general practitioner. The illustrations are many, and clear and distinct. As all text-books give the compiler the chance to express and ventilate his own experience and ideas, so Dr. Noyes has done with himself, and as his experience has been a large and advantageous one for many years, that which he presents is instructive and interesting.

Pamphlets.

Maltine with Pepsin and Pancreatine. Professional Testimonials. The Maltine M'f'g Co., New York. This pamphlet contains some strong testimony from leaders in the profession, concerning this useful preparation.

Knowledge. A weekly magazine "Devoted to supplying information such as one seeks in his cyclopedia and fails to find there, because it is not up to date." A good idea; depending on the way it is carried out. The present number contains items from Bowen to Crooks, including one on the Republic of Brazil. Publisher, John B. Alden, New York.

In Lippincott's for July:

Edward Heron-Allen, the well-known expert in palmistry, has an interesting article upon "The Cheiromancy of To-Day," in which he gives a clear and concise account of how knowledge of character of personal attributes may be derived from a study of the lines, and mounts, and general formation of the human hand.

Mrs. Bloomfield-Moore contributes an important article on "Keely's Contributions to Science." Mrs. Moore gives an idea of the subtle nature of the force with which Keely has to deal, and explains the causes of the delays which have again and again disappointed both the inventor and his supporters.

We have received from the State Board of Health a series of precautionary circulars, for use in case of emergency. They will be forwarded to any address on the receipt of a two-cent stamp, on application to the secretary, Dr. Benjamin Lee, Philadelphia, Pa. They consist of precautions against Consumption, Typhoid Fever, Contagious and Infectious Diseases, Scarlet Fever, School Hygiene and the care of Infants.

The Medical Digest.

Trombetta, of Messina, has had a successful case of splenectomy. One day after the operation both red and white corpuscles began to increase in number.

Exalgine has been given by Atkinson (*Brit. Med. Jour.*) in twenty-four cases of various forms of neuralgia, with very unsatisfactory results.

Sprains, however severe, are treated by Riches (*Jour. de Méd. Prat.*) by fifteen minutes' immersion in hot water, repeated daily, followed by the application of a rubber bandage and massage. He reports good results.

Hummer, of Geneva, has rediscovered Corning's method of procuring cocaine anæsthesia and avoiding the risk of toxic effects, by confining the cocaine to the tissues to be anæsthetized by the employment of rubber cords and bandages.

Extreme Dryness of the Tongue is a distressing symptom, which does not readily yield to treatment while the concomitant cause remains in operation. For this condition, Blackman (*Brit. Med. Jour.*) gives pilocarpin, gr. $\frac{1}{20}$ to $\frac{1}{10}$. The effect is delightful.

Balsams are usually supposed to cause irritation of the urinary organs, when given in large quantities. Stockman (*Brit. Med. Jour.*) has made some investigations concerning balsam of Peru, storax, benzoin, and tolu. As a result, he considers it proved that all these can be given in as large doses as are ever desirable, without any risk of producing albuminuria or nephritis. They never cause enough irritation to injure the healthy kidney, although they may irritate one already diseased. In some cases, a resinous body from the balsams has been mistaken for albumen.

At the Société de Biologie M. Roger presented a paper of much interest. His investigations have been upon the substances which increase the virulence of certain microbes. He inoculated rabbits with pure cultures of symptomatic anthrax, to which this animal is ordinarily refractory. But if one injects at the same time the liquid of a sterilized culture of micrococcus prodigiosus, the anthrax develops rapidly and the animal dies.

Moreover, in injecting very attenuated cultures, which have become inoffensive, of pneumococci and streptococci, but adding one or two drops of a sterilized culture of pneumococcus prodigiosus, M. Roger has seen the pneumococci regain all their virulence and the animal succumb to these two injections, either of which alone is harmless.

He has succeeded in isolating from these cultures of micrococcus prodigiosus the principle which so powerfully stimulates microbic virulence. It is soluble in glycerine, from which it is precipitated by alcohol. Wash with alcohol and ether, and dry rapidly. It is a yellowish powder, which has the double property of liquefying gelatin and modifying the immunity of animals. It appears to be composed of two ferments—the first liquefies gelatin, and loses its power when heated to 60° for half an hour; the other favors infection, and can be destroyed only by a temperature of at least 130°, sufficiently prolonged. This substance, injected into the veins in doses of one or two drops, abolishes the immunity acquired by an animal.

It is known that Rossbach demonstrated that the tissues of animals poisoned by a large dose of papaïn are full of microbes, showing that the spores accompanying the papaïn develop admirably in the medium created by this ferment. Roger, introducing into the veins papaïn in non-lethal doses, has found that they favor the increase of virulence of attenuated cultures, such as those of pneumococcus and anthrax, in the same manner as the sterilized cultures of micrococcus prodigiosus.—*Revue de Ther.*

TREPHINING FOR GENERAL PARALYSIS. — Shaw and Cripps (*British Medical Journal*) give the history of a case upon which they had operated last July. After this he went on very favorably; his mental condition improved greatly; he was cheerful and able to read several hours consecutively; his memory improved, and he had no recurrence of the convulsive attacks. The motor symptoms did not improve. So well did he appear mentally that his discharge was ordered, when, on February 14, he had a strong attack of convulsions, and lay in a comatose state till the 20th, when he died. During this last attack there was some pulsation, but no bulging over the trephine hole. At the post-mortem, the orifice was found to be filled with a dense, fibrous membrane, which prevented bulging, and six ounces of fluid were obtained from the brain. It would have been good practice to have operated again.

ROUTIER describes a case of fracture of the cranium in the left fronto-parietal region, without external wound, resulting from a fall. Immediately after the injury the patient was giddy, but could regain his bed. Some hours later he was in complete and profound coma. Sensation much retarded on the right side, hemiplegia, contractures, incontinence.

The gentle and gradual production of coma, the sensory troubles and hemiplegia, led Routier to believe that there was a compression of the brain due to a clot, without doubt from a lesion of the middle meningeal artery. This decided him to have recourse to the trephine, which he applied over the left Rolandic region. He found a fracture of the cranium and removed a clot weighing seventy five grammes. But he could not tie the artery which was wounded. He decided to check the hemorrhage by tamponing with iodoform gauze and suture the skin, to secure compression.

Five hours after the operation consciousness had returned to the patient, as well as motion. But the next day there was complete aphasia, which endured as long as the compression by the gauze was maintained. When the latter was removed it was found that it had compressed the angle of the convolution of Broca. This compression removed, the patient recovered his speech in two hours. Complete recovery ensued in a very short time.—*Revue de Ther.*

SURGICAL TREATMENT OF PULMONARY TUBERCULOSIS.—Tillmanns, at the Berlin Surgical Congress, showed a patient whom he had two years previously cured of tuberculosis of the left lung and pleura, by extensive resection of the front part of the chest wall. The patient seemed in the last stages of phthisis. The left lung was highly phthisical, the pleura adherent; in the sputum numerous bacilli were found. The left pleura contained an empyema of two and one-half years' duration. Several fistulas traversed the chest wall, which was also tubercular. The heart was dislocated to the right. The right lung was comparatively healthy. The preceding two and one-half years the patient had spent mostly in bed. Repeated resections of ribs had been made, but failed to cure the empyema. On May 27, the front part of the left chest wall was resected *in toto*, for an extent of five to twelve centimeters, from the second to the sixth rib, close to the sternal borders. The width of the portion removed was five centimeters at the upper part, and twelve at the lower. The whole left pleura was highly tubercular, the lung phthisical and only as large as a man's fist, and firmly adherent. The lung was partly covered by a skin flap taken from the thorax. The pleura was energetically scraped with a sharp spoon, and stuffed with iodoform gauze. June 22, after repeated curetting, the pleura was converted into a cutaneous cavity, by transplanting skin, after Thiersch's method. Local treatment of the lung proved unnecessary; the organ shrank steadily, and the tuberculosis underwent a spontaneous cure. The patient was discharged cured July 23, and has remained well ever since; and now presents a blooming appearance.

—*British Medical Journal.*

DRS. MCKENDRICK, COATS AND NEWMAN, reviewing the report of the Hyderabad Commission on Chloroform, summarize their points of agreement as follows:

1. We are agreed that death from chloroform occurs by failure of respiration, and that this is probably the most frequent mode of death.

2. We are agreed that chloroform causes a gradual fall in the blood pressure as registered by kymographic tracings from the carotid artery. This is the normal effect of chloroform.

3. We are agreed that when chloroform is pushed this gradual fall may be so great as to become in itself "dangerous." This is admitted in Paragraph (8) of the Hyderabad Report, where they state that after an animal has been involuntarily holding its breath "the grasping respiration which succeeds then causes very rapid inhalation of chloroform, with immediate insensibility and a rapid fall of blood pressure, *which quickly becomes dangerous.*" (The italics are ours.)

4. In addition to this, which we may call the normal effect of chloroform on the heart and blood pressure, both of us observed peculiarly sudden and unexpected falls of pressure, with slowing of the heart. We are agreed that this phenomenon occurs, and the Hyderabad tracings show that it is frequent. We differ as to the cause of its occurrence. The Hyderabad Commission ascribing it to asphyxia, while we contend that neither in the time of its occurrence after holding the breath, nor in its general characters, does it correspond with the fall of pressure due to asphyxia Whatever be the explanation, the occurrence is in itself sufficiently serious, and should not be minimized as forming one of the sources of danger in the administration of chloroform.

—*Brit. Med. Jour.*

A DIETETIC PROBLEM.—While the fact has been well recognized for centuries that domestic plants and animals are subject to modification under cultivation, and that most of the species now existing are the results of methodical selection and intelligent supervision, we are very slow in learning to appreciate the fact that man himself can be similarly improved. Some recent experiments upon feeding swine, undertaken under the auspices of the State of Michigan, have shown not only the well-known fact that the proportion of fat in the body is dependent upon the manner of feeding, but also that the vigor and development of muscles and bony skeleton can be varied at will by the selection of appropriate food. Moreover, it was shown in these experiments, as might indeed be expected, that the feeding of the sow, previous to and during pregnancy, had a great influence upon the size and vigor of her litter, and upon their subsequent power of resistance to disease.

Popular belief holds that the size of the child and its strength are largely influenced by the diet of the mother, and that her unsatisfied desires for certain

articles of food may even produce physiological or pathological changes, such as deformities or mothers' marks. The theory has been lately advanced that even the sex of the child may be determined in a similar manner. The statement being that by feeding one parent so as to have an excess of vitality over the other, the sex of the offspring will be that of the less vigorous parent. There are some facts offered in support of this which render it very plausible. Such a result, as every one knows, is brought about in this way among the bees. At all events, it shows, if true, the all-prevailing influence of dietics. If we can, by proper food given to the mother during pregnancy, prevent rickets, defective teeth, marasmus, and all the evils of defective vitality in the offspring, and even influence its sex and development, is not this subject worthy of more attention from the profession than it has yet received? If intelligently pursued with all the light of modern science, may we not hope for the most beneficent results to the race? If neglected, can we doubt that physical and moral degeneration will overcome our highest nations as well as the most ignorant savage?—Woodbury, *Dietetic Gazette.*

SOUTHAM thus describes his method of operating for stricture of the urethra by internal urethrotomy:

Operation.—The instrument I always employ for division of the stricture is Teevan's urethrotome, which is carefully carbolized. The patient having been anæsthetized, about a drachm of carbolic oil (1 in 16) is injected into the urethra. A ferret is passed through the stricture, and the urethrotome having been screwed on to this and made to follow it, the roof of the urethra at the point of constriction is divided from before backwards in the usual way. The instrument is then withdrawn, together with the ferret, and the stricture is aftewards dilated by passing Lister's sounds, 9–12 to 12–15. A full-sized silver catheter is then introduced into the bladder, and the urine having been drawn off, the viscus is thoroughly washed out several times by injecting a saturated solution of warm boracic acid. About two ounces of the solution are left in the bladder, and as the catheter is withdrawn the urethra is also flushed out with the lotion. An iodoform bougie is then passed down the canal as far as the neck of the bladder, so that it may lie in contact with the urethral wall at the seat of division of the stricture. During the operation especial care is taken to protect the patient from exposure to cold, and in addition to the ordinary precautions the lower extremities are wrapped up to the hips in thick woolen bandages.

After-treatment.—As soon as the patient recovers from the anæsthetic, ten minims of liquor opii sedativus are given, and the dose is repeated in a few hours if he is at all restless and complains of pain. He is directed to hold his urine for six or eight hours, if possible; at the end of this period, when he is allowed to pass it himself, the urine will generally come in a good stream. For a time micturition is attended by more or less pain and smarting, and in most cases the urine will be slightly stained with blood for the first day or two after the operation. On the following morning, if there is no sickness from the anæsthetic, the boracic acid mixture, which had been discontinued on the day of operation, is commenced again. On the fourth morning, either a cocaine bougie or a drachm of a 10 per cent. solution of cocaine is introduced into the urethra, and, after an interval of ten or fifteen minutes, Lister's sounds, 9–12 to 12–15, well carbolized, are passed through the stricture. By means of the cocaine the pain which usually attends the passage of an instrument for the first time after operation is more or less completely prevented. During the remainder of the patient's stay in the hospital Lister's sounds are passed daily, and before leaving he is himself instructed how to pass a No. 9–12, which he is allowed to take away with him, so that in the future he may keep the stricture dilated by the occasional passage of an instrument, and therefore be independent of further surgical assistance. The average length of time spent in hospital after the operation in the six cases referred to was twelve days.

Contra-indications.—I am of opinion that internal urethrotomy should not be performed in cases where the urine is alkaline and offensive, containing a large amount of pus, nor again in cases where it remains so after a course of boracic acid administered internally and continued for a fortnight or three weeks. When these conditions exist, they usually point to the presence of a severe form of chronic cystitis. Under these circumstances the stricture, if it does not yield to dilatation, is best treated by external urethrotomy, and at the same time the crystitis can be relieved by draining and irrigating the bladder through the perineal opening. Provided that the urine is acid, I believe that a slight amount of pus in the urine is not a bar to internal urethrotomy; for this condition was present at the time of operation in four of the six cases above referred to.—*Lancet.*

THE NEED OF NOURISHMENT IN CHILDREN OF DIFFERENT AGES[1] (Dr. Camum, of Urach).—The subject may be divided as follows: 1. Their complete wants; 2. The needs of each nutritive substance (albumen, carbohydrates, and fats.)

Under the first head the several functions of the body (especially the temperature of the skin, the elimination of water by the lungs, and by muscular action when working, are only possible by a continuous generation of a sufficient quantity of energy in the body, the only source of which is the food.

If an adult, in a state of rest, averages in a day 2,400 heat-units (or 100 per hour), during the performance of the different functions, and inversely, just so many heat units would have to be produced, as the temperature of the body is nearly constant.

100 grammes (1,500 grains) of albumen and 100 grammes of carbohydrates always give 410 heat-units; but 100 grammes of fat, 930 heat-units, through decomposition in the body (on condition that these materials are supplied by the so-called "mixed diet."

From theoretical views, as well as experiments made, it is highly probable that, in men idle and working, the differences in size and age, the elimination of force, and therefore force-production, is nearly proportional to the area of the skin under similar external conditions and in like exertions.

The skin-area, represented by "O," can be used in the formula found by Vierordt-Meeh, taking the weight "G."

$$O = 12.31 \text{ kilos } (G) \times 9\frac{2}{3}.$$

The calculation of the amount of heat produced is made from the nourishment consumed, allowing for the growth of the children and from the organic constituents found in their urine and fæces.

In the following tables, the calculations for adults are from Kubner; the seven cases of infants nourished by their mothers' milk, and the five cases of older children were under my own personal care, and were systematically observed through a period of twelve

[1] Translated by H. Hamilton, M.D., Harrisburg, Pa., from *Deutsch. Med. Wochenschrift*, May 22, 1890, No. 21.

years. Upon a square meter (1.20 sq. yds) of the surface of the body), the following number of heat units were produced in twenty-four hours:

TABLE I.—ADULT MAN.

	At rest.		At labor.			Ave. toil of old gray-headed man and wife.
	H'ng'ry	Satisfi'd	Movement of the body.	8 hours easy toil.	8 hours hard toil.	
Heat-units.	1134	1189	1210	1400	2300	1100

TABLE II.—MOTHER SUCKLINGS.

The babies on their mothers' nourishment only in the first three months furnished the least relative amount of heat, most likely due to their being especially well taken care of, and also because little movement was required of them. While in the older children the decrease in the relative quantity of heat commences about the time they begin to attend school and are compelled there to sit still.

TABLE V.—INFANTS ON MOTHERS' MILK.

Age (end of)	Mos.	1	2	3	4	5	6	Man at easy labor.
		grams

TABLE VI.—OLDER CHILDREN ON MIXED DIET.

Age (years).	2	3½	6	7	8	10	12½	14	Man at easy labor.
Absolute amt. of org. sub. consumed.	186	211	257.3	295.3	280.5	321.5	375 7	399.	671
100 parts of org. substances consumed are: albumen	25.3	21.6	20.7	22.4	19.4	18.3	19.7	20.3	18.4
carbo-hydrat.	51.6	60.7	68.3	66.4	68.8	70.6	72.0	70.7	73.7
fat.	23.1	17.7	11.0	11.2	11.8	11.1	8.3	9.0	7.9
100 parts of above produced heat-units as fol's: albumen.	21	18	18	21	17	16	18	18	16.7
carbo-hydrat.	42	49	60	56	60	62	65	64	66.9
fat.	37	33	22	23	23	22	17	18	16.3

In the artificially-nourished sucklings (not taking into account the observations of Bildert upon infants of one to three months), the heat equivalent was unusually large.

To explain this condition, we must consider that the work of digestion demands a certain amount of energy, and in unsuitably (un-naturally) fed individuals very considerable amounts of force, thereby greatly impairing the usefulness of the food to the organism.

The composition of the food being given, the above tables were constructed (see tables v and vi).

From the foregoing tables a correct estimate can be made of heat elimination from the surface of the skin, noting the weight and age of the baby; hence its need of nourishment and the composition of the food it should have, provided it is not either too light or heavy for its age.

RUSSIAN NOTES.

TRANSLATED BY C. D. SPIVAK, M.D.

THE EFFECT OF PILOCARPINE IN TRAUMATIC DEAFNESS, AND ITS COLLATERAL EFFECTS. (Dr. O. E. Appelberg).—I am prompted to publish the following case in view of the fact that since my announcement in June, 1888 (*Novosta Terapii*) of the effect of pilocarpine upon the restoration of hearing, like reports do not cease to appear from time to time; but, as to its collateral effects, no mention is anywhere made.

K. K., peasant, thirty years old, well built and preserved, received a scalp-wound while working in a shaft, from the fall of a piece of wood. The wound was at the border of the hairy part, to the right of the median line, parallel to the sagittal suture, about two and one-half inches long, and reaching the periosteum. The wound healed quickly. The patient, soon after the accident, became deaf in both ears, and blind in the only eye he had. In order to talk with the patient, it was necessary to bring the lips close to the ear of the patient and speak in a very loud voice. His vision was so impaired that he could not count his fingers at a near distance. Examination gave negative results. Patient complained of dizziness, headache, ringing in the ears; was apathetic, and suffered from insomnia. All the means used to restore sight and hearing (pot. brom., strych., nitroglyc., etc.) did not produce any effect, and only chloral was given for insomnia. On the 22d of June commenced treatment by pilocarpine injections (pilocarp., gr. iij to aquæ, ℈viij.)

June 22. Watch closely applied; ticking feebly heard by right, none by left. Injected one-fourth of a spritz syringeful of the above solution. In two to three minutes salivation; no sweat.

June 23. Hearing same. Injected one-half a spritz. Copious sweat and salivation. After the sweating, complained of chill.

June 24. Right ear hears ticking at a distance of one and one-half centimeters; left, when closely applied. Injected three-fourths of a spritz. Sweat, salivation and chill.

June 25. Hearing same. Full spritz. Copious salivation and sweating; chill.

June 26 and 27. Status quo. Injected same. After-effects same.

June 28. Subjective feeling of patient raised; vivacious; glad to hear the signal bell. Full spritz; same phenomena.

June 29. Left ear hears ticking at considerable distance: right same. Full spritz; same phenomena.

June 30. With both ears hears the ticking at quite a distance. When talking to him loudly, he hears at a distance of one foot. Full spritz; same phenomena.

July 1. Status quo ante Ordered solution of pilocarp., gr. iv to aquæ same Sweat and salivation more copious; chill.

July 2. Hears the ticking with both ears at a distance of five and one-half centimeters. Same phenomena.

July 3. Hearing same. Full spritz; phenomena same. While being treated by pilocarpine the constipation disappeared. Complained that during the night some one pricked him with a needle through the wall. To convince him of the impossibility of such a thing we did not succeed

Having recalled to memory the article in the *Novosti Terapii*, in the case of Waugh,[1] where ext. fluid folior. Jaborandi was given with the collateral result of mania persecutivæ, I suspected the same in my case. To my sorrow, in such a wilderness as this Siberian *Taiga*, I could not collect more literature on pilocarpine.

In the Pharmacologie of Herrmann, Kohler, Nothnagel and Rossbach, in the text-book of Schopera, comparative tables of the effects of drugs by Berlioz, and an old pharmacology by Sakolovski, I could find nothing.

Seeing the favorable action of pilocarpine on the restoration of hearing, and knowing, from the case of Waugh, that the collateral effect of pilocarpine will cease with the discontinuation of the drug, I continued the injections daily.

July 4. Hearing same. Complained that he was being pricked again; that his toes were besmeared with something by somebody; that the "boys play tricks on him."

July 5, Morning. Hears better than yesterday; can be talked to without raising the voice. The same complaints.

Evening. The phenomena of mania persecutivæ increased; hallucination by day; being pricked, smeared, and persecuted. Pilocarpine discontinued. Hears even a whisper. At night complained that cold water was being poured on him all the time. Insomnia; chloral.

July 6, Morning. Complains, "I have no rest; wherever I go, they pour water on me." After administration of chloral, slept. Towards evening became calm.

July 7. Hallucinations as before. Insomnia.

July 8. Excitable; refuses to take medicine; chloral in alcohol (to deceive him), pot. bromide. Towards evening calmer.

July 9. Status quo. Refuses medicines. Insomnia. Fears everything and everybody; everybody talks about him.

July 10. Status quo.

July 11. Calmer. Only hallucination of hearing left.

July 12. Status quo.

From 13th to 18th, the hallucination decreased.

On the 19th no hallucination. In a few days was discharged, with normal hearing.

—*Russkaya Medicina.*

[1] This case was published during 1887, in the *Medical World*. It is doubtful whether the mental phenomena there detailed were directly due to the jaborandi, or to its effect in forcing a secretion of milk which nature had never been able to sustain previously.—W. F. W.

"Three Seasons of Koumiss Cure in Shabo" is the title of a lengthy article by M. B. Scherr, which appeared in three consecutive numbers of the *Medicina*.

Gospodin (Mr.) Scherr gives the history of the introduction of koumiss into Russia, and tells us that the first pioneers were the Tartars of Crimea and Caucasus. The pharmacists Mai and Dubovski were the first to recommend it to the public at large in Odessa. Now there are in Odessa three institutions where koumiss is manufactured, but none is under the supervision of a medical man.

The mode of producing koumiss, as done by the Tartars, is as follows: A piece of bread is masticated well, and then exposed to the air under a temperature of 34–40° R. The sugar produced by the action of ptyalin on the starch is therefore a favorable soil for the generation of lactic acid bacteria. The bread is introduced into the horse-milk, and, as soon as fermentation sets in, it is bottled and hermetically sealed. Sugar is added in order to cover the sour taste of the excess of lactic acid.

The mode of preparing koumiss practised by Gospodin Scherr is as follows: Two parts of pure barley malt and one part of wheat flour is mixed with a sufficient quantity of water of a temperature of 50–52° R., and placed in an oven for two or three hours, where the temperature is not higher than 48°. The mixture is gradually cooled down to 40°, and left for a few hours to ferment. The spores of lactic acid bacteria find their way into the mixture and generate lactic acid fermentation. Should there be a doubt as to the existence of lactic acid spores in the room, the walls are smeared, a night before, with cow's milk. Then the mixture is suddenly cooled down to 20° (in order to avoid the generation of butyric acid, for which the temperature of 20°–30° is most favorable), and ten per cent. yeast in some form is added. The fermentation is considered complete when half the amount of the sugar is decomposed. Then the ferment, wrapped in gauze, is introduced into freshly-obtained horse-milk at a temperature of 24°, and left to ferment for twenty-four hours in open vessels, and then bottled and sealed.

During the three seasons, Dr. Scherr had under koumiss cure 274 patients, of whom 204 were consumptives. He gives the following results: 204 patients—74 males, 130 females; 22 cured, 76 improved, 96 no change; 10 died in Shabo. The average number of days passed in Shabo, 105; average number of bottles of koumiss drunk by each patient, 140; average increase in weight, 7 pounds.

Medicina, Nos. 10, 11, 12, 1890.

Richet finds that in rabbits the development of tuberculosis is delayed by introducing the blood of the dog into the peritoneal cavity. His results are very curious, and point to practical applications of the greatest interest. He inoculated ten rabbits with an equal quantity of tuberculous material. Two, also, received a certain quantity of blood in the peritoneum. A third received, instead of blood, an infusion of dog's liver. Three other rabbits served as objects for comparison. The three latter became thin and feeble, no longer able to stand up. That one that received the infusion of liver was a little less affected. The two which received the blood were alert, look well, and had gained 1,560 grammes in weight; while the two controls had lost four hundred and forty grammes. Finally, however, all died; but those which received the blood survived much longer than the others—even for many months.

—*Revue de Ther.*

Sysol is recommended by Gerlach, as a bactericide more powerful than phenol or creolin, less poisonous than either, and cheaper. It may be used either upon the body or as a disinfectant for closets, etc.

Hervieux strongly advocates the substitution of the goat for the calf as a source from which to obtain vaccine virus. The reasons are: The danger of inoculating with the virus of tuberculosis, to which the bovine race is very prone, and the fact that the goat is not liable to tuberculosis.

Maminoff recommends the helianthus aunnus as a remedy for ague. He gives ten to twenty-five drops of a strong tincture made from the fresh flowers and bark, one part to five of menstruum. The fever fell the next day, and disappeared in three days. In recent cases one day's treatment sufficed. No bad after-effects occurred.—*Revue de Ther.*

The discussion in Paris over the relative virtues of kola and caffeine has resulted in a challenge—not to the field of Mars, but to the icy heights of the Alps. Duhamel proposes that Sée and Lapicque shall designate an *alpiniste*, who, with him, shall ascend Mt. Blanc, the alpiniste to have no nutriment but caffeine, while Duhamel sustains life with his kola biscuits. Thus the comparative effects of the two agents may be definitely ascertained.

—*La Tribune Méd.*

Grancher advocates a special antiseptic regimen for those ill with contagious diseases. Believing that contact rather than diffusion in the air is the method of transmitting germs, he surrounds each patient with screens of metallic netting; provides him with a full set of all articles used by him, which are appropriated to his exclusive use; he is placed in a supplemental infirmary, exclusively devoted to such cases, and the most careful and severe prophylactic measures are enjoined upon the attendants. To disinfect objects used by the patient Dr. Grancher provides a stove with compressed steam, boiling water or the liquor of Van Swieten acidulated.

—*Revue de Ther.*

Hypertrophy of the Heart During the Period of Growth.—The treatment varies much. We have seen children to whom quinine and iron were given to combat the palpitations which were thought to have induced the hypertrophy and which were attributed to anæmia, chlorosis, or dysmenorrhœa. But this is all based on a careless examination. The treatment which has always answered with us has been the combination of digitalis and iodide of potassium; the digitalis in the dose of ¾ grain of the powder, in infusion, and the iodide to the amount of 3¾ to 11¼ grains.

The hygienic treatment differs according to the age of the patient. In childhood we direct a diminution of the work—mental and physical—and a nitrogenous diet. In youth the hypertrophy not being compensatory, but simply physiological and exceeding the requirements, we can, without fear, advise exercise, and labor—manual and intellectual.

—*Revue de Ther.*

FRENCH NOTES.

By A. E. Roussel, M.D.

Mercurial Flannels.—Intended to replace the use of frictions with mercurial ointment in the treatment of certain forms of syphilis. We take a piece of thick but soft flannel, which we soak in a solution of carbonate of soda; it is then washed out, taking care to preserve a slight alkalinity; after which it is plunged in a solution *d'azotate mercureux;* it is then withdrawn from this bath and immersed in ammoniacal water; the mercurial salt is decomposed, and the flannel becomes grayish black in color; it is then allowed to dry, but not exposed to the sun's rays; after which it is placed in an air-tight vessel.

Twenty-five centimetres of this flannel are applied on the skin of the chest and abdomen. The patients inhale the vapors which are thrown off, and which are well supported.

—*La Médecine Moderne.*

Intra-venous Injections of Quinia in Malaria.—According to Prof. Bacelli, this method of treatment, employed with antiseptic precautions, constitutes the most prompt and efficacious means of treating the pernicious form of malarial fever.

After having applied a ligature to the arm, Bacelli injects into one of the larger veins forty to sixty centigrammes of the following solution:

R.—Chlorhydrate of quinine	1 grm.
Chlorate of sodium	75 centig.
Distilled water	10 grm.

—*La Bulletin Médical.*

The Treatment of a Red Nose.—One-fifth of the cases, according to Unna, are due to acne rosacea, with vascular dilatation; it has often a direct connection with seborrhœa of the scalp; this seborrhœa should be treated by the ordinary methods.

When acne rosacea is present, Unna administers fifty centigrammes of ichthyol internally, and prescribes at the same time aqueous lotions of the same substance. The following is also used:

R.—Zinc ointment	20 grms.
Powdered rice	5 "
Sulphur	2 "

Unna also advises punctures of the dilated venous trunk with Hebra's instrument, repeated two or three times a week. The use of ichthyol soap is also indicated. Warm water alone should be used.

—*Revue de Thérapeutique.*

A Non-bitter Solution of Quinine (M. Lutz.)

R.—Sulphate of quinine	0.50 grms.
Dilute sulphuric acid	0.50 "
Essence of mint	5 gtts.
Saturated solution of saccharine	10 grms.
Distilled water	90 "

—*Journal de Médecine.*

A Strange and Fatal Disease.—This disease is more fatal than yellow fever. It is called the black fever in some countries. It has played havoc in Honduras and in the southern part of Central America. A hospital which has just been erected near the proposed line of the Nicaragua Canal has some two hundred victims. One-half of them will probably die. The black fever comes almost as suddenly as a stroke of lightning and there is no relief. If you attempt to get out of the country you would not survive and you must remain quiet and take your chances. The first symptoms are burning sensations, and before you have been afflicted two hours you feel as if you were being roasted alive at the stake. Unless the black fever disappears from that country, or a cure is found for it, the loss of life will be appalling.

Medical News and Miscellany.

ALCOHOL has gone up in price.

KOSSUTH is affected with cataract.

DR. J. J. O'NEIL is at Sea Isle City.

DR. W. H. TRUMAN is at Asbury Park.

DR. J. W. SHOEMAKER is at Ocean City.

DR. H. H. BIRNEY is at Cape May Point.

DR. HOFFMAN is at his Long Branch cottage.

DR. TOMLINSON, of Plainfield, takes in Europe.

DR. TINSLEDT, of New Brunswick, is at Seawaren.

DRS. B. B. WILSON and E. Price are at Longport.

DR. DE. BAUN, of Passaic, climbs the White Mountains.

READING'S first sunstroke this summer occurred June 26.

DR. D. MAGIE, of Paterson, goes to West Hampton, L. I.

DR. P. M. BERNARDY died last week, aged eighty-five years.

DR. PIERSON, of Orange, has gone to Europe for his health.

DR. VAN RIPER, of Passaic, tours with his family in Europe.

DR. ELLA PRENTISS UPHAM has located at Asbury Park.

DR. GREEN, of Elizabeth, spends a month at Bass Rock, Mass.

DR. T. B. WELCH, of Vineland, has a visitor from Timbuctoo.

THE Spanish doctors say their young king has hydrocephalus.

DR. R. P. LINCOLN, of New York, is at leafy Netherwood.

DR. CARMAN, of Englewood, tramps through the Adirondacks.

DR. MACKENZIE and wife, of Metuchen, are tripping in Canada.

DR. A. MEYER, of New York, has taken a cottage at Long Branch.

DRS. D. L. WALLACE AND TICHENOR, of Newark, summer at Belmar.

DRS. MATHEWSON of New York, and Morrell, have climbed to Summit.

DR. SCHOTT, of Philadelphia, has purchased a cottage at Atlantic City.

DR. VAN SHOTT, of Passaic, betakes himself to Saratoga's happy lake.

A CASE of beriberi has turned up at Brooklyn on a vessel from Macassar.

DR. ARCHER, of Allendale, July's at Greenwich, Conn., while his townsman, Dr. Osborn, goes to France.

ELEVEN nurses graduated from the Training School of the Episcopal Hospital.

MENTHOL is recommended by Gottschalk in the hyperemesis of pregnancy.

CHARLES BARTON, Business Manager of the Casino, is sick with diphtheria.

MEDICAL DIRECTOR A. L. GIHON sails for Europe to-day, to stay till September.

DR. C. A. FRANCE, of Manayunk, is spoken of as a candidate for the Legislature.

THE leper returned from Boston to Liverpool, has been sent to her friends in Sweden.

DR. DELL BURGESS, the only American physician of Havana, is at Richfield Springs.

LEPROSY exists in every Australasian colony excepting Tasmania and New Zealand.

STUDENTS matriculating at Vienna are required to present their photographs to the dean.

DR. TAYLOR, of Ridgefield, has penetrated the wild and woolly West as far as Colorado.

DR. J. J. SULLIVAN, of Passaic, treats himself to a summer's botanizing in the Adirondacks.

DR. STRAYER, of Roaring Spring, Pa., will be nominated as an Assemblyman of that place.

DRS. A. FRICKE and D. G. Brinton divide their time between Atlantic City and Philadelphia.

THE German Reichstag boasts four doctors, while the French Chamber of Deputies swarms with them.

DR. WILLIS G. WESTMORELAND, editor of the *Atlantic Medical and Surgical Journal*, died on June 27.

AN eleven-year-old boy in Woburn, Mass., died of hydrophobia last week; two months after being bitten.

DR. RICHARD A. EVANS has been renominated for Superintendent of Public Instruction at Springfield, Illinois.

QUEEN MARGARET COLLEGE, Glasgow, will open a fully-equipped medical school for women next October.

DR. CHAS. O'REILLY, of the Toronto General Hospital, sailed from New York for England, June 4th.

MORPHINE habitués may escape the consequent morning sickness by adding one-third grain of cocaine to the dose.

AT the University of Aberdeen, the General Council proposes to throw open every class to women, without restriction.

F. A. DAVIS, of Philadelphia, will publish the Annual of American Medical Sciences for 1890, within a short time.

DR. W. H. DALY is off for New Brunswick after the salmon. ℞. Picis liquidæ, ol. hedeomæ, āā q. s. M. S. For punkies.

THE Editorial Department of the July number of *The Dietetic Gazette* will be under the charge of Victor C. Vaughan, M.D., Professor of Physiology in the University of Michigan.

DR. J. P. COCHRAN, of Detroit, has been elected Supreme Medical Examiner of the R. C. Union of Knights of St. John.

THE Jefferson Medical College, of Philadelphia, has conferred the degree of LL. D. upon Dr. Robert Battey, of Rome, Ga.

THIN emphasizes the frequency of abdominal diseases in the tropics, by remarking that there disease strikes below the belt.

DYSENTERY is becoming seriously prevalent at Norristown. Dr. Cresson has been employed to analyze the drinking water.

DR. OUSELEY SMITH, of London, attempted suicide in Boston, because he failed to secure a supporting practice the first week.

THE *Alabama Age* tells us, the manganese mines mentioned in a recent issue are located in Calhoun county, Ala.; and not S. C.

THE General Medical Council (London) has objected to registering the diplomas of the University of Glasgow in Public Health.

The Board of Health is earning the gratitude of the neighborhood by compelling the removal of the piggeries at Wheat Sheaf Lane.

MODERN SCIENCE deals some pretty hard blows at ancient traditions. St. Bernard's Well has been pronounced unfit for drinking purposes.

THE Children's Hospital Dispensary, at the Mary J. Drexel Home, has treated 948 patients since opening, and only gave 225 prescriptions.

URSINUS COLLEGE has conferred the degree of Ph.D. upon Prof. J. M. Anders, M.D., of the Medico-Chirurgical College, of Philadelphia.

AFTER July 1, physicians desiring to practice in New Jersey must go to Trenton, pass an examination, and pay a fee of $15, before doing so.

THERE is a long list of doctors at Ocean Grove, but they are not the kind that interest us, being the doctors that preach but don't practice.

DR. E. B. O'REILLY is now acting as Medical Superintendent of the Toronto General Hospital during the absence of his brother in Europe.

MERCURIALS have advanced in price from three to eight cents per pound. A significant fact. We are on the verge of a new "calomel fad."

THE crew of the British steamship Gloucester City have suffered severely from dysentery, brought on by the use of the Delaware water for drinking.

DRS. L. WEBSTER FOX, A. Somers Bradford, of London, Theodore Fasset, and D. L. Benjamin, of Washington, are registered at Atlantic City.

THE article on The Dietetic Habits of Some Great Singers, by Chas. Avery Welles, in the June number of *The Dietetic Gazette*, is well worth reading.

THE Ptomaine produced by the bacillus of mice septicæmia is called methylquainidine. One-thirty-second of of a grain is sufficient to kill a rabbit.

DR. J. J. MOYLAN, of Philadelphia, has been staying at the Waverly, Atlantic City, and Dr. James Walton has taken a cottage there for the season.

ON the Hotel Kaaterskill register appear the names of Drs. Mason, of Troy; Barclay, of Newburgh; R. H. Johnson, of Germantown, and Skene, of Brooklyn.

THE "Country Home" for invalid children is this year to be a seaside home, at Point Pleasant, N. J. It is under the charge of the Sisters of All Saints, No. 2034 Cherry street.

DR. H. H. BIRNEY was married to the daughter of Dr. J. K. Boude, of Washington. Among the guests in attendance were Drs. White, Mead, Crows, Hollingsworth and Presbrey.

THE *Record* says that a virulent bull fever will commence to develope within the month; but we do not therefore advise physicians to grab their satchels and run for the Stock Exchange.

DR. C. H. FISHER, of the State Board of Health of Rhode Island, sails about July 22 for an extended trip through Austro-Hungary, Italy, Switzerland, France, Germany and Great Britain.

THE University of Florida was founded May 30, at Tarpon Springs. Among the incorporators are Hamilton Disston, Jacob S. Disston, A. P. Stafford, F. H. Davis and Dr. Charles E. Sajous.

"DR." A. F. Richter has been arrested for practising without registration. He claims to have graduated at the University of Bonn, Germany, but to have left his diploma in that country.

SUNSTROKE is beginning to figure in the mortality records. Five fatal cases were reported in St. Louis June 27, and nine on June 26, while twenty persons were prostrated in Chicago on June 27.

IN the *Alabama Med. and Surg. Age* for June appears an account of the birth of quadruplets; this remarkable occurrence happens about once in three hundred and seventy-five thousand births.

THE Royal Humane Society has awarded a medal to Dr. Bray, for jumping overboard and saving the life of a brother physician. The profession is probably not overcrowded on the African coast.

VISITORS at the Berlin Congress will find THE TIMES AND REGISTER on file in the reading-room, richly freighted with the news of each successive week, as it relates to the medical profession.

MISS MITCHELL, of Kingston, a graduate of Queen's University, who received a license to practice medicine a couple of months ago, is the first woman in Canada to write M.D. after her name.

DR. JOHN A. WYETH, of New York, has been visiting his parents and friends in Marshall county, Alabama. The doctor is a native of Alabama and has many warm friends in that part of the county.

LONG BRANCH enjoys her share of the doctors' patronage. On her hotel registers we find the names of Drs. T. H. Bailey, Caldwell, and J. A. Williams, of New York, and W. W. Moorhead of Philadelphia.

A NUMBER of young ladies, graduates of Vassar and Smith Colleges, have organized a college settlement in the slums of New York, where they are making an effort to civilize the wild children of the neighborhood. Bath-rooms, free medical advice, lessons in sewing, cooking, and kindergarten, are among their means of elevating the neighborhood. Dr. Caroline Hamilton has her offic in the building.

Six days of drudgery's heavy wheel she stands,
The seventh sweet morning folds her weary hands,
Yes, child of suffering, thou may'st well be sure
He who ordained the Sabbath loves the poor!—Holmes.

DR. RICHARD DOUGLAS, a prominent young physician of Nashville, has the assurance that he was the most popular physician in attendance at the American Medical Association; as the result, he received a fine surgical chair.

DR. MITCHELL, of Bayonne, is drawn to Lake George by the canoe meet; while Dr. Taylor, of the *Medical World*, searches the Maine woods for bear meat, though he would probably see more of it at Narragansett Pier.

A GOOD vintage is expected in the south of France, Burgundy, Algeria and Spain; while in Charente, Auvergne and Franche Comte the insects have done harm to the vines. Reports from the champagne country are favorable.

AN English Rector, who has been living among the Druses and won their confidences, states that from their knowledge of Freemasonry he believes this people to be descendants of the Phœnicians, who aided Solomon in building his temple.

LAST Saturday's European steamers carried with them Prof. A. P. Brubaker, and Drs. Carl Buttner, S. C. Gordon, J. Glazer, O. A. Judson, J. Price, J. Stewart, H. W. Schreiber, N. Senn, J. W. Williams, W. J. Younger, E. M. Coy, J. W. Johnson and J. W. Wilson.

THE *Medical Press* calls attention to the overcrowded condition of London cemeteries, where over a million and a quarter of bodies have been buried in less than three hundred acres of ground. Persons contemplating dying should make a note of this and avoid London.

THE London doctors are having a good deal of fun with Dr. Sherman, our whilom fellow-citizen who cures hernias. He has been arrested and fined for claiming the rank and title of a doctor in medicine. He now advertises as a "specialist for the treatment of rupture, though not a physician."

DR. WILLARD PARKER, not less eminent as a sanitarian than as a surgeon, was so impressed with the belief that the daily watering of the streets increased the foulness and insalubrity of the atmosphere, that he gave orders to arrest any one who should be seen sprinkling the street in front of his residence.

THE present movement to give a full three days' holiday when July 4 comes on a Friday is one which is to be heartily recommended. Let employers give their employés some privileges and they will work all the better for it. The old saying still holds good: "All work and no play makes Jack a dull boy."

MADAME SARAH BERNHARDT had a narrow escape from death in London, last week. She returned to the Savoy Hotel, where she is stopping, at an early hour from the theatre and retired. Finding it impossible to sleep, she determined to take chloral, but by accident took 120 grains, which was an overdose, and the disastrous effects were soon apparent. She appeared to be dying, and several physicians were immediately summoned and remedies were at once applied. It was four hours, however, before any marked improvement was perceptible in Madame Bernhardt's condition and she was pronounced out of danger.

A MEMBER of the English Parliament appears to have done something useful. He has invented a method of separating gold from the ore by means of electricity. The two great difficulties in the ordinary process, the deficient access of the gold to the mercury, and the action of other metals upon the latter, are both overcome.

JOSHUA LACY, a farmer near Birmingham, killed himself by falling with a pencil in his mouth, the point of the pencil penetrating his throat causing hemorrhage and blood poison. It is often a comparatively easy matter for a man to write himself to death with a pencil, and even an old goose quill with only one flange has downed many a promising statesman.—*Alabama Med. and Surg. Age.*

THERE have been many attempts at defining loneliness. Our Mr. McMullin is alone "apart from her he loves"; another is "lonely since his mother died"; "alone in crowds to wander on"; "lone and delighted, like a dried-up mullein-stalk in a sheep-pasture"; "mid pleasures and palaces lonely I roam;" etc., etc. But for an accentuated illustration of the malady we commend you to the doctor who isn't going to the Berlin Medical Congress.

IN an infusion of hay Dr. Kitassato has discovered a new microbe which produces a sensation of smell similar to that of musk. A culture of this germ is at first slightly red, later tile-colored. It thrives best on bread, rice, or potato, but may be cultivated in the ordinary way. The culture has holic tincture of the culture. There are therefore now known bacteria which produce colors, light, poisonous alkaloids, and, lastly, odor.—*Chemist and Druggist.*

THE CITY'S HEALTH.—During the week ending June 28 the interments reported in Phlladelphia were as follows:

Cholera infantum	93
Marasmus	42
Phthisis	39
Inflammation of stomach and bowels	31
Convulsions	25
Pneumonia	22
Bright's disease	21
Debility	17
Heart disease	17
Old age	17
Inanition	16
Inflammation of brain	15
Cancer	10
Congestion of the brain	10
Typhoid fever	10
Casualties	8
Bronchitis	8
Paralysis	7
Apoplexy	6
Hemorrhage	6
Suicide	6
Cholera morbus	5
Cyanosis	5
Diarrhœa	5
Peritonitis	5
Other causes	80
Total	526
Total for preceeding week	480
Corresponding week in 1890	493
Adults	220
Minors	306

IN a recent club meeting, the subject under discussion being "Charity," Dr. Mary Putnam Jacobi startled the society by asking: "Why, in this labor-protected country, in the absence of war, pestilence and famine, with work and land for every one for the doing and the asking, should there be so much

need of almsgiving? Would not a little more justice make much of our charity unnecessary?" When Dr. Jacobi is approached she offers a certain sum for the completion of a piece of work requiring immediate despatch. In the majority of cases the offer is declined.

One of the best ways of committing involuntary suicide is to make haste in hot weather. This is especially true for old or fat people. Hot weather is in itself a strain upon the system in civilized countries. In America, where almost every one is in a hurry, and in Chicago, where a person that is slow of movement excites comment and is regarded as a curiosity, no one seems to know that haste makes waste. In hot weather we should be as calm and philosophical and move as leisurely as possible. Eat slowly, and eat but little meat, drink no alcoholic fluids, don't get excited, and under no circumstances run for a train or a street car.—*Chicago Herald.*

At the meeting of the Trustees of the Philadelphia Polyclinic and College for Graduates in Medicine last week, an agreement was signed whereby the Nurses' Beneficial Association will furnish and perpetually endow a room for its members who become sick in the pursuit of their calling.

The Ladies' Aid Society's first payment towards the fund to perpetually endow a free bed for cripples was accepted. The Isaac B. Thorn memorial free bed was established by a perpetual endowment fund received from Mrs. Isaac B. Thorn.

Over $11,500, it was said, will be required to paint, plaster, and finish the new building in the fall, and efforts to raise that amount are being made.

The furniture for thirteen rooms has already been donated.

The *Cin. Med. Jour.* gives the following "Disease Catalogue of Syria:" The most prevalent affection met with in Syria is malaria, both inland and on the coast. Paludism, in an acute form, attacks infants as well as adults, complicated with dyspnœa and stimulating croup, though without objective throat symptoms. Sulphate of quinine is the remedy most in vogue, and is prophylactic against a second attack. Next to malaria, syphilis; and especially hereditary syphilis is frequent; also dysentery and diarrhœa. Alcohol, climate, and unwholesome food are responsible for the latter affections. Pulmonary emphysema is likewise in order, due to excessive smoking probably; and ophthalmia, liver disease, calculi and leprosy liberally contribute to complete the Syrian destructive bill of fare.

To Contributors and Correspondents.

All articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from June 15, 1890, to June 28, 1890.

Appointments in the Medical Department, U. S. Army.—To be Ass stant Surgeons, with the rank of First Lieutenant: Frank R. Keefer, of Pennsylvania, June 6, 1890, *vice* Woodruff, promoted; Thomas U. Raymond, of Indiana, June 6, 1890, *vice* Newton resigned; Henry D. Snyder, of Pennsylvania, June 6, 1890, *vice* Wilson, resigned; Allen M. Smith, of New York, June 6, 1890, *vice* Matthews, promoted; Ashton B. Heyl, of Pennsylvania, June 6, 1890, *vice* Hall, promoted; Joseph T. Clarke, of New York, June 6, 1890, *vice* Porter, resigned.

By direction of the Acting Secretary of War, Major George M. Sternberg, Surgeon, will, in addition to his present duties, perform the duties of the post-surgeon at Fort McHenry, Maryland, during the absence of that officer on leave.

Leave of absence for one month, to take effect the 15th instant, is granted Captain L. W. Crampton, Assistant-Surgeon. Par. 5, S. O. 75, Department of the Missouri, St. Louis, Mo., June 9, 1890.

By direction of the Acting Secretary of War, Captain John De B. W. Gardner, Assistant-Surgeon, having been found incapacitated for active service by an Army Retiring Board, will proceed to his home. Par. 12, S. O. 135, A. G. O., Washington, June 10, 1890.

Leave of absence for one month, to take effect on or about June 15, 1890, is granted Captain Aaron H. Appel, Assistant-Surgeon, Fort D. A. Russell, Wyo., with permission to apply, through Headquarters, Division of the Missouri, for an extension of one month. Par. 4, S. O. 42, Headquarters, Department of the Platte, Omaha, Neb., June 10, 1890.

Leave of absence for one month, on surgeon's certificate of disability, is hereby granted Captain Marcus E. Taylor, Assistant-Surgeon, with permission to go beyond the limits of this division, and to apply for an extension of five months. Par. 1, S. O. 45, Division of the Pacific, San Francisco, Cal., June 13, 1890.

By direction of the Secretary of War, leave of absence for six months, to take effect when, in the opinion of his department commander, his services can be spared, is granted Captain William O. Owen, Jr., Assistant Surgeon. S. O. 139, par. 12, A. G. O., June 14, 1890.

By direction of the Secretary of War, First Lieutenant Eugene F. Swift, Assistant-Surgeon, is relieved from duty at Fort Spokane, Washington, and will report in person to the commanding officer, Fort McDowell, Arizona, for duty at that station, relieving Captain Marlborough C. Wyeth, Assistant-Surgeon, who, on being thus relieved, will proceed to Fort McIntosh, Texas, and report in person to the commanding officer thereof for duty at that station. The officers named will also report by letter, upon their arrival at their new stations, to their respective department commanders. Par. 10, S. O. 140, A. G. O., June 16, 1890.

By direction of the Secretary of War, leave of absence for two months, to take effect July 1, 1890, is granted Captain Charles B. Byrne, Assistant-Surgeon. Par. 13, S. O. 141, Headquarters of the Army, A. G. O., June 17, 1890.

By direction of the Secretary of War, leave of absence for four months, to take effect upon the final abandonment of Fort Maginnis, Mont., is granted Captain William W. Gray, Assistant-Surgeon. Par. 14, S. O. 141, Headquarters of the Army, A. G. O., June 17, 1890.

Culbertson, Howard, Captain (Retired.) Died June 18, 1890, at Zanesville, Ohio.

By direction of the Secretary of War, Major Samuel M. Horton, Surgeon, will visit the encampment of the Maine Volunteer Militia, at Augusta, Maine, during the period of encampment, June 30 to July 4, 1890, inclusive, for the purpose of instructing the medical department thereof in its duties in camp, and, on completion of this duty, will return to his proper station. S. O. 143, par. 5, A. G. O., Washington, D. C., June 19, 1890.

By direction of the Secretary of War, Major Charles R. Greenleaf, Surgeon, will attend the encampment of the Pennsylvania National Guard at Mount Gretna, Pennsylvania, from the 18th to the 26th of July, 1890, for the purpose of accompanying the Surgeon-General of Pennsylvania in his inspection of the camp. Par. 11, S. O. 144, A. G. O., June 20, 1890.

By direction of the Secretary of War, leave of absence for three months and fifteen days, to take effect as soon as his services can be spared, is granted Captain William C. Borden, Assistant-Surgeon. Par. 11, S. O. 146, A. G. O., June 23, 1890.

TUBERCULOSIS.[1]

BY ERNEST LAPLACE, M.D.,

Professor of Pathology and Clinical Surgery in the Medico-Chirurgical College; Visiting Surgeon to Philadelphia Hospital, etc.

ONE of the most remarkable signs of advancement in medicine has been the tendency of finding the same cause as the starting-point of various affections, and hence of greatly simplifying the proper knowledge of the case. What we formerly knew as scrofulosis, coxalgia, white swelling, lupus, tubercular meningitis, etc., are now all classed under one head—namely, tuberculosis. Last, but not least, fistula in ano may be tuberculous.

Germs were found to be living bodies belonging to the vegetable world, and grow just as seeds do. A grain of corn falling on good ground produces fruit of its kind; but falling in unsuitable soil produces nothing. So with germs. They must find a suitable soil in which to grow or they do not reproduce themselves.

The old lady who is now before us has lived to a good old age, and has been protected from germs by her robust constitution; but, through hardships and exposure, vitality has diminished, and now she affords a good soil for the germs which she once resisted. This is a case of acquired scrofulosis. Every day we breathe the germs of tuberculosis, and the reason we are proof against them is that our lungs are not then a suitable soil for their development. What, then, is scrofulosis, bot hin the child and in this case?

These germs invade the economy and lodge in the places most suited for their development, and produce an irritation. The lymph glands are the most favorite seat of the trouble. Germs nestle in the gland, develop among the cells, cause an irritation, proliferation, and death of the cells. A cheesy or fatty degeneration takes place, and we have the first step in the pathological process. The process continues, and we have a tubercular abscess formed, which will, in time, open itself at the point of least resistance, just as was the case in this old lady.

When the process goes on beyond hypertrophy, you have this fatty degeneration becoming purulent, when it must be opened or allowed to open itself. When you do not interfere with these glands they suppurate; but when they are taken out with aseptic precautions the condition is removed, and union by first intention may be obtained. This lady is so old, and has so many suppurating glands, that we will not operate. All that can be done in this case is to stimulate her, improve her strength, and open the abscesses.

When a patient can stand it, these glands should be removed, for the longer they are allowed to remain the greater will be the chances of a general infection of the lungs, and the risk of miliary tuberculosis.

I next bring before you this robust looking man, whose cervical glands all along the deep jugular vein of the left side are enlarged. There is a long string of glands, and great care must be exercised in their removal. An incision is made along the anterior border of the sterno-mastoid muscle, and the glands are exposed.

This case has already waited too long and the glands have begun to suppurate. The glands are usually attached loosely to the cellular tissue, unless there has been previous inflammation, and it is better to remove them by the fingers than by dissection. Gentle compression will check all hemorrhage; but we should use the hemostatic forceps when necessary. Strict antiseptic measures will be observed, and I will

[1] Delivered, April 12, 1890, at the Philadelphia Hospital. Reported by W. B. Stewart, M.D.

recommend that a 10 per cent. solution of iodoform and ether be applied to every part of the wound. In this way the iodoform penetrates every nook and corner. The body heat causes the iodine to be liberated, and this kills the germs. This should be done in every case.

Simply sew the wound up with a deep suture, to hold all the parts together, and a continuous suture on the surface to cause perfect union. A continuous suture expedites matters. Place a small drainage-tube in the wound. Dress antiseptically, with a dry iodoform dressing. The deep suture will relieve all strain on the superficial sutures, and no scar will remain.

COXALGIA.

This little child has the very same affection as our last two cases, although different in appearance. These germs of tuberculosis, instead of invading the lymphatic glands of the neck, have invaded the hip-joint, and developed the disease known as coxalgia. These very same germs developed in the cartilage and ligaments around the head of the femur, caused vegetations, irritation, and destruction of the white corpuscles, that come there by diapedesis. A large, disintegrated mass is formed, which will find an exit in time.

It has been a mooted question just when to interfere with tuberculosis of the hip-joint. The indication is to operate just as soon as fluctuation can be detected. When pus is present it is best to remove it. In this case we can tell this much—we will find disease vegetations and the so-called "pyogenic membrane."

A point to be remembered is this: The presence of pus is the result of a pathological condition; for pus may be produced in the hip-joint just as in any other part of the body, as the bone is freely supplied with blood-vessels. This case belongs to a class of operations that are not brilliant, for we cannot restore the diseased joint to its natural physiological condition. We can remove the local trouble but not the diathesis. The present operation may result in a tubercular focus starting in another part of the body. An incision is made over the right hip-joint, and a free flow of pus results. Mucoid degeneration of tuberculous tissue and vegetations are all scraped away with the curette. As much of the dead bone is removed as is deemed necessary.

The focus of the disease having been removed, it is hoped that the remaining carious bone will be restored to a healthy condition; and we will trust to nature to heal the wound with healthy granulations.

Original Articles.

A FURTHER STUDY OF HERNIA.[1]

By A. W. RIDENOUR,
MASSILLON, OHIO.

THE study of hernia is one of the most interesting, one of the most important, and one of the most frequent of all the subjects the medical man has to contemplate. This is rendered so by the great number of cases existing, and the great amount of suffering endured by those so afflicted. I trust, therefore, that I need hardly apologize for again bringing it before you. It would hardly become me to tell you that I will instruct you in this paper; but my experience since last appearing before your body with a paper on this subject has been instructive to me, and I always deem it the duty of medical men to give their brethren the benefit of their experience, be it for weal or woe.

An earnest, thoughtful study of this subject is necessary "ere we can hope to arrive at a satisfactory conclusion as to the best permanent relief combined with absolute safety." This is and should be the ultimate aim of our endeavors.

We cannot hope to accomplish this in a day, nor by rash attempts, without a thorough understanding of our subject in all its bearings. A thorough knowledge of the case, a thorough knowledge of the procedure necessary to effect permanent relief, must be prerequisites. Downright earnest work is as essential to success in this as in everything else.

We shall devote a brief time to the discussion of the symptomatology and diagnosis of the various forms of hernia, including in this description some conditions that modify and change the character of a hernia after it has passed the inner barrier. We will next discuss the mechanical treatment, including under this head the prognosis as applied to those changes that occur during the progress of a hernial protrusion. The consideration of treatment other than mechanical will be then noted, giving a synopsis of the modifications adopted by different operators.

In discussing symptoms of hernia, it will be necessary to bear in mind the various forms of hernial protrusion, as the simple, oblique, inguinal, femoral, umbilical, etc. A tumor is usually noticed on inspection, although in rare instances a small knuckle of bowel may be present in the canal (having passed the internal ring), and may even be strangulated and no tumor be found. The tumor will have an elastic or doughy feel, as there is present fluid in sac or not; will feel dense and inelastic, not doughy, if omentum be present alone. Where slight strangulation exists, in addition to pain and digestive disturbance, the parts, as skin and connective tissue, will show evidence of slight inflammatory action. The parts will be more sensitive; skin with a slight blush; the tumor will feel more tense, more elastic, *more immovable.* Slight anxiety will be shown on countenance of patient.

The location of the tumor will guide you somewhat as to the variety of hernia, although a femoral hernia may be mistaken for an enlargement of one of the femoral glands; but, in general, the greater density of a glandular enlargement, combined with the entire absence of all digestive disturbance, will serve to distinguish, especially as the density, if a hernial protrusion, would be indicative of slight strangulation, and there would be added an elastic, tense feel to the tumor, besides the *immobility*. The size, if omentum, as it may closely assimilate a tumor, would also serve to distinguish, as an omental tumor is rarely so small as an enlarged gland.

Too much stress should not be placed on the reducibility of a hernial tumor as a distinguishing feature, as many hernias are not reducible. The symptoms and diagnosis of a severe case of strangulation are so plain they need not be repeated here; but the slighter forms—and I include in this category all those where *pressure* is a feature, either by a truss or an irreducible sac, or thickness and organization of sac itself causing slight congestion or severe of bowel, or irreduction of bowel, with constant pain and the usual resulting digestive disturbance—demands attention, and will be considered shortly.

The mechanical treatment of hernia dates back to the earliest trace of man. In the caves of prehistoric

[1] Read before the Ohio State Medical Society, June 6, 1890.

man there has been found the remains of a truss : the supposition was that it was made in the Iron Age, as that metal evidently entered into its composition. A further slight evidence that the wearer was a laboring man was that the portion passing around the body was somewhat rusted. The remains of this truss were fished from beneath the débris of defunct bacterial skeletons. I merely mention the longevity of this truss to impress on your minds its early use.

Where a hernial protrusion is threatened—as indicated by pain in this region on exercise, with maybe a slight impulse on coughing—a truss, well-fitting, but not to exercise an irritative pressure, and applied over the cotton-gauze, silk, or flannel undershirt, should be at once applied and worn day and night. A duplicate should be worn when bathing.

When the hernia is recent, and presents itself as a simple hernial tumor, readily reducible, with rings or openings not too relaxed or large, and the muscular system not relaxed, a truss will be applicable, as above.

In children, in recent cases, it is advisable to apply a truss. While the kind of truss recommended is important, yet there are so many kinds, all having the same object in view—viz., the retention of the bowel—that it is only necessary to say, when the hernia is of such a character that one well-fitting truss fails, you will find all will fail.

The character of a rupture (with complications) is to be considered as the important element in affecting the final prognosis, and treatment other than mechanical, or with the combination of the mechanical and operative. It is unfortunate that all cases presented to your notice are not recent; hence, do not present the simple forms we have glanced over.

A rupture may be old ; the sac and pillars, canals, and rings may have undergone changes that you find necessary to recognize, and which will determine your line of treatment. In recent cases the sac is merely a prolongation of peritoneum ; but, sooner or later, it becomes thickened, organized, loses its smooth, shining structure internally and externally, and forms dangerous adhesions, both external and sometimes to lumen of bowel; becomes irreducible—a fixture. The bowel soon recognizes the difference between returning surrounded with the smooth surface of sac and the condition about to be described. When the sac becomes irreducible, the bowel begins to create slight friction in its passage over it, and this friction begets congestion, with diminution of the secretion ; soon followed by thickening of the sac, organization, especially at the internal opening; the bowel finds greater difficulty in returning, and soon you have a mild case of strangulation from pressure by the sac. This condition is not always coincident with irreducible bowel ; but is invariably associated with *pain, severe, aggravated at each attempt to wear any kind of a truss.* The patient is a constant sufferer from indigestion, obstinate constipation, becomes nervous, and is a good subject for suicidal mania.

To advise a patient to wear a truss under such circumstances is pernicious, and entitles the one so advising to the suspicion of ignorance at least. Many of these patients persist in the attempt to wear a truss without medical advice, or resort to the truss-makers, who affect to be able to cure them by means of their special contrivance. Ignorance is now associated with egotistical pecuniary greed, and the patient goes from one to the other, constantly growing worse, and, finally, one of three things takes place : either the bowel becomes in fact severely strangulated, or the attempt to wear a truss is abandoned, the bowel becoming irreducible, a fixture out, and the patient lives a miserable existence, with his whole energies, mind, and body concentrated on his rupture, to the utter exclusion of all business, all work ; becoming, in fact, a dependant, living a mere existence ; or, the surgeon or experienced medical man is finally consulted, who diagnoses, first, an irreducible sac; second, the conditions which naturally follow. It may be a matter, therefore, of the utmost importance to diagnose this condition, with a view to your intelligent prognosis and recommendation for proper treatment.

An adherent sac may be diagnosed. Replace the bowel ; when, if the sac does not return, you will still be able to feel the membrane, the walls of which will glide readily over each other distinguishably between the fingers, besides being, in recent cases, even slightly thicker than the parts feel when entirely free from sac. Another diagnostic symptom is the slight prominence yet remaining of the parts after bowel has been replaced ; and still another : persistence of pain in handling the parts.

I have thus referred to the *irreducible sac* and the conditions which follow invariably ; there is no compromise, unfortunately. The pillars undergo changes in old cases of rupture ; they become atrophied. This atrophy is gradual ; but, nevertheless, certain, and, by involving all the muscles entering into the formation of the walls of the canal or opening, will facilitate the persistence and growth of a hernial tumor to prodigious size, and is due not so much to the hernial pressure direct as by the interference of circulation, both arterial and nervous, from an ill-advised truss. This atrophy will clearly modify your treatment also, as will, later on, be discussed.

The canal, in old cases, becomes materially shortened, but its width is increased in proportion. The length from internal to external opening may be only the mere fraction of an inch, but it may be one, two, or more inches wide. The rings become relaxed, dilated from a fraction of an inch to two or three inches, and become by atrophy a mere thread.

In a femoral hernia, the anatomy of the parts being somewhat different, there is not so perceptible a difference in the outlines of the external opening, owing to the more inelasticity of Poupart's and Gimbernat's ligaments. The pillars are here also more tendinous in structure, and will modify your treatment, as we will endeavor to show in the proper place. You will not notice so perceptible an atrophy of the structures entering into the formation of a femoral hernia, and hence your tumor will not grow to the large proportions found in inguinal. The sac will, however, undergo the same changes.

In umbilical hernia, the condition of the muscles and musculo-tendinous structure, entering into the formation of the walls of the opening, will allow of the largest sized protrusion of bowel or omentum, or both.

Before we pass to the proper treatment of hernia other than merely mechanical, it may be considered important to consider the contents of the sac ; as, while it will not affect the outcome, it will affect or modify the treatment. The sac may contain bowel alone. It may contain omentum alone. It may contain both. When bowel alone is found, the case is clear. When omentum alone, active or severe strangulation probably never takes place ; but an irreducible omental hernia is the rule, with scarcely an exception. The omentum does not wait for the sac to become first adherent, but adhesion between the meshes of omentum occurs on short stay beyond the

limits of the internal ring, and the mass must either return *en masse* or remain out, which it generally does. The truss business works well here in creating disorder.

The combination of bowel and omentum is an unfortunate one. Active strangulation of the bowel will soon follow, with irreduction of either, and care is needed in your operative procedure to not lose sight of the bowel feature; in fact, this complication exists so often that bowel should always be searched for in every case of omental hernia.

The prognosis of simple recent hernia, when seen at once or early, say within a month, in children or adults, or between the ages of birth and fifty-five years, is good in so far as death is concerned, provided a truss is worn constantly, or, at all events, when the patient is in the upright position, and continued through natural life. Can we hope for a relief in these cases with the truss? Yes, for a while; but the child who has a rupture, and after treatment with a truss for two, or may be four, years is considered cured, will, when arriving at adult, or may be middle, age, have a return, may be sooner; this applies also to the adult when reaching old age.

The prognosis in old cases, or those not attended to properly where changes have taken place in the sac, or the hernia is large, scrotal, irreducible, painful, or when truss will not readily retain sac, bowel and omentum, or in the condition I have dwelt upon above, is bad, very bad, and these are the cases that demand something more than the truss treatment. A combination of operative with mechanical means. It may seem strange that this combination should be recommended. Why not depend on the results of the operative alone. Now, while not in the least detracting from the purely operative, it is necessary to show cause sufficient why a combination is better, in some cases, at least, but certainly not imperative in all; but in the old, always; in middle life, where the patient is a laborer, or of active habits; in the young adult for the same reason; in childhood, after the tenth year, for the same reason, it is imperative. In women, whose habits are not so active, the combination may be omitted, as the closure of opening is usually better done, owing to the necessity of allowing no pressure on the cord or vessels in the male. I usually, however, advise the combination in the female. You will remember, I noticed the atrophy of the pillars in cases of long standing, that is, in those not classed under the head of recent. Now, union between opposing atrophied pillars, and between atrophied muscular walls of the hernial opening, is certainly not so firm as it would be between muscles of full tonicity, and it makes no difference whether you interpose granulative tissue, or unite skin to pillar, that union is not, and cannot be, firm under this condition; and, hence, will sooner or later give way. I will not apologize for admitting that experience has made it necessary to depart from the purely operative in these cases under consideration, and classed as above. You will remember that in my former paper stress was laid on the purely operative, except in very old people. I now, for the above sufficient reason, advocate, or rather practice, the combination plan.

In discussing the operative procedure as a vital part of the combination plan of treatment, we will premise all the usual description of the scrub brush, by saying, use thorough cleanliness and strict antisepsis in performing the work and conducting the after-treatment.

The incision varies in length from two to four inches; the dissection is carried down to the sac, which is opened carefully, exposing the contents. If bowel is present alone, it should be returned, unless in case of gravest form of strangulation, of long and dangerous continuance, when, if after exposing more of it than is included in the strangulation (after enlarging the seat of stricture) to the influence of hot cloths, the vitality does not return in the least, it should be resected; but as this will, in all probability, result in the death of the patient, it should certainly be a *dernier ressort*. It is astonishing the vitality of the bowel under such circumstances, but there is a limit, and subsequent ulcerative enteritis, with perforation and death, is to be taken into account. It has been my misfortune to lose one such case, as result of delayed operation from mistaken diagnosis on the part of the attending physician. Should the contents prove to be omentum alone, it should be ligated first internal to internal ring, or, after pulling down, to healthy omentum; the stump returned after all bleeding has ceased. Where purely omentum and close adhesions have formed to sac, I do not hesitate to treat the sac and omentum as one, but should bowel and omentum both be present, expose the bowel in all cases, replacing it, then treat the omentum as above.

Having emptied the sac, what shall be done with it? The necessity for this question seems to arise from the diverse ways in which it is treated, for instance: It has been reduced bodily within the abdominal cavity. It has been left in the canal, where firm adhesions prevent its return. It has been ligatured, the hernial investment amputated, and stump returned. It has been ligatured, amputated, and then invaginated in the canal.

It has been drawn up upon itself, fixed as a bulwark against the internal ring. It has been twisted upon itself and left in the canal. It has been interwoven into the fibrous structures of the pillars.

Riedel ties the sac as high up as possible, leaving the ligatured portion below to help fill the distended canal.

Nusbaum, Sewel, and Czerny, tie the sac high up, and remove all below the ligature. Mitchell Banks favors the latter method. Ball twists the sac and leaves it in the canal. Bryant interweaves it in the pillars. We pause now and decide which of these different methods is the best. You all agree to do something.

Should the sac be forced from all its adhesions and ligatured high up, you will agree that the portion below the ligature will slough out soon. You will all agree that if you twist the sac sufficient to have it remain so, it will die and slough off. You will all agree that if you interweave the sac between the pillars sufficient to have it remain there, and any attempt made to close the wound it will slough off. You will probably agree that it will slough anyhow after interweaving, whether the wound is closed or not. You will agree that if you draw it upon itself and fix it as a bulwark against the ring, it will slough off.

It is favoring the rapid return of the hernia, to replace it bodily within the cavity. It is favoring the rapid return of the hernia to allow it to remain intact.

Then the alternative is left of cutting it off and thus doing away with it altogether. Now, we have the most sensible solution of the treatment of the sac—banish it. We will then loosen all adhesions, draw it down until you get up to healthy peritoneum if possible; suture it carefully at this point, cut it off immediately below, ligate any bleeding joints, or twist the bleeding vessel; then allow the sutured end

to glide within the opening ; it is always preferable to use sterilized cat-gut for this suture, on account of its ready absorption. It may happen that from the density, thickness and intimate interblending, it is impossible to go up so far as to reach healthy peritoneum, you will then go as high as possible. I will illustrate this impossibility by this specimen of sac I now show you. You notice that at the point of amputation, the sac, or rather neck of same, is fully one-quarter inch thick ; it was so firmly adherent as to be impossible of moving, hence I was forced to cut it off, after suturing as described. This specimen was obtained from a gentleman, aged sixty-eight, who suffered for years from an irreducible sac ; latterly, finding life a burden, and not being able to wear a truss any more, for obvious reasons, connected with the sac I have above shown, consulted me with this result ; here is the sac, and the patient, now a happy man, with good appetite, works on his farm every day, and wears a truss as a precautionary measure. You will notice a small sac lying in the bottom of the bottle, this was obtained from a young lady with marriage in view, who told me "She did not want her man to marry a cripple." She is now well, happy and wears a truss, although it was not necessary to wear one in her case, as the rupture was small and the pillars firm ; openings closed firmly and readily. Before the operation she wore a truss with difficulty ; pained her, and bowel persisted in escaping to side of truss.

Having disposed of the sac, we will examine the canal and pillars. It is better to remove all superfluous aneolar tissue in the canal ; in fact, I do not hesitate to remove the sides and roof of tunica vaginalis, even the sheathes of the pillar muscles ; removing with curved scissors the membranous rings, cremaster muscles ; bringing thus bare freshened pillar wall to bare pillar wall ; a little time spent here in thoroughly doing your freshening and cleaning the canal and muscles is well spent ; and avoid injuring the cord and accompanying vessels in the male and the round ligaments in the female, or the larger vessels of a femoral hernia ; if in the latter, do not waste your time freshening Poupart's or Gimbernat's ligament, as they will not unite, neither will the cordy, tendinous structures immediately above them.

The next step in the operation is closing the wound. I am aware that a decided difference of opinion exists in this. There are those who attach the utmost importance to the open, or, at least, partially opened method. They allege that by suturing the integument to the pillars on each side, and allowing the bottom of the wound to heal by granulation, the result will be better, that the hernia will be less liable to return. This is, as yet, a matter of opinion, as the method has not had the inexorable test of time and circumstances, hence, no positive opinion should be predicated on assumptive evidence ; allbeit, success seems assured. There are objections to the open method that will bear discussion. The first is as to the firmness and permanence of granulation tissue. In general, granulation tissue is extremely liable to accidents and disease. How often do old wounds of soldiers and others, that have healed by granulation, open out again ?

How many of you have not seen cases of erysipelas causing wounds to re-open after months of apparent security ?

Granulation tissue is tender, the experience of the old soldier with granulated stump attests this fact. No artificial limb can be borne. Should a rupture recur a truss could not well be worn, the condition of the patient then becomes pitiable. Wounds that heal by granulation heal slowly. There is a vast difference between direct union between the pillars and the interposition of treacherous granulation tissue, in addition to the absence of the more tender integument.

The cicatrix resulting from direct union is not tender, is much firmer, and a truss can only be borne without pain or inconvenience when direct union is obtained. In additon, the impression made on patient and friends is different in the open method. You have a ghastly, unsightly wound staring them in the face for weeks, which will scare friends from undergoing the operation. In the direct union you will find patient and friends cheerful. It is not a fact that in direct union the danger of septic poisoning is greater. Sirs, the directly opposite is the truth, the whole truth, and nothing but the truth. The wound heals at once, and there is no chance for septic poisoning.

You have thoroughly cleansed the bottom of the wound, brought the pillars into exact apposition, placed strands of catgut over the pillars, allowing them to protrude at lower end of wound. Catgut is one of the very best materials for suturing the sac and pillars, better than silk even ; it will hold sufficiently long for union to take place, and there is avoided that danger from non-absorption. And above all else avoid trying to form a new canal for the cord and vessels, as advocated by an Italian surgeon. Italy is reponsible for many innovations, this is one of the newest and one of the most treacherous of her exports. Place your sutures at intervals of half an inch and commence at upper end of your incision, ending at lower, and you will not regret prefering direct union to unsafe granulation tissue.

In femoral hernia, use deep and superfical sutures in one, to cause the integument to unite to the parts, beneath. An early operation in umbilical hernia is advisable for obvious reasons. An acute strangulated rupture should be operated on at once, and right here let me interject a word regarding that miserable subterfuge—taxis. Suppose you should finally succeed in reducing the bowel, you are only prolonging his agony ; operative relief must come sooner or later, and the sooner the better for that patient's health and happiness.

The question now arises, Will we let the patient go about his business without any precautionary support ? In children, a support may be unnecessary, but in the adult, if a laborer, or one who is active on his feet ; or in the aged ; or in cases of long standing, where the pillars and muscles are atrophied, it will be necessary.

The union between atrophied muscular tissue is easily torn. The support may be a band around lower portion of abdomen, but a light truss is, perhaps, better, worn in day-time along with only light pressure, merely sufficient to keep the bowel from infringing on the internal surface of the cicatrix, or slight depression necessarily existing on the inner surface of the sutured sac ; no amount of care in suturing the sac will entirely prevent this depression, any one to the contrary notwithstanding ; hence, it is better to efface the depression by a little gentle pressure from the outside. A light truss thus worn as a precautionary measure, will not cause absorption of the union between pillars or the cicatrix, if the latter is not granulation tissue, and not, hence, covered by normal integument ; always, therefore, endeavor to save the integument ; cause it to unite in the median line ; this cicatrix is firm, and no truss will affect it in the least, neither will the truss increase the weak-

ness between the union of atrophied pillars, but when the pressure is light will actually strengthen them. I am fully aware of the opposite grounds maintained by some in this, but am prepared to bring the test of time in support of my position. I have operated sixty times for the relief of hernia; twenty-five times when severe strangulation existed; ten times when slight strangulation existed, and twenty-five times where no strangulation either by sac or rings existed. A few of the latter annoyed the subject simply from the difficulty in retaining the bowel with truss, and in a few instances, where bowel and omentum were present, but an early operation prevented any strangulation of bowel.

In three cases death resulted; two of them in operation for severe strangulation; one of these should have been operated at least three days before—I referred to it above; the other one was suffering from acute gastritis at time of the severe strangulation, an operation made at any time prior to this would have saved his life. The third case of death was for slight strangulation, caused by the sac; patient had local peritonitis and general ascites. The local peritonitis aggravated, if not caused, by persistence in the truss attempt; patient could scarcely walk; was very obese; weighed two hundred and sixty pounds; lady forty-five years; died on the seventh day from general peritonitis.

Fifty seven recovered. In none of these fifty-seven did any serious symptoms arise. Fever was an exceptional symptom; the majority had none at all; none had any severe pain; the wound healed in from one week to two in all; all were up during the third week.

Ten of these cases were double operations (both sides at one operation); fully one-half of the patients were females. I find in running up my results that I need not feel my labor has been in vain. My first operation for strangulated hernia was made in 1871; only slight attempt at closure was made in this instance, and the sac was replaced without ligation after being opened, and the bowel replaced. My sutures were passed to include the pillars, and skin tied externally. After one year, rupture returned, (patient was a hard-working man). I advised a truss, which he wore for the next ten years. Recently, this patient tells me, he does not need a truss any more, as the bowel does not return, but I told him to wear a light one, or band, while at work. Since then, my attempts have more and more assumed elaboration, with a view to better secure permanent relief, but I am still pleased with my first attempt. I have lately examined fifteen, whose operations date back five years, and of these I find eight are still sound, and have worn no support of any kind; all active working people, men and women; two of them past sixty. I have recommended all of them to wear a light support in future. Seven are failures in that a rupture has returned, and these seven wear trusses, and claim no discomfort, and can do hard work with no trouble whatever from the truss. None of these seven would have had a return had a light truss been recommended at once.

In nine examinations, after nine years have elapsed since the operation, four are still sound, with no rupture, not even an impulse or coughing; five have had a return of the rupture, they wear trusses which readily retain the bowel, and suffer no inconvenience. In two that I examined after ten years have elapsed since operation, one has a rupture easily retained with a truss; the other has no tumor, but an impulse simply claims the rupture was out, but that since wearing a truss does not show any more. All the cases are in an infinitely better condition than before operation. Then life was a burden—now a real pleasure. As one man said to me not long ago, "I would not take $20,000 and go back where I was before you operated on me." I have been told similar words many times by these patients.

Some ten years ago I attempted the Heitonian method of injecting the sac. I met with five failures in five cases, and have operated on all five since by the knife route. You will notice in the sac I exhibit to you, an ecchymosis well marked at the upper portion of the neck, this is sufficiently explanatory of the condition calling for an operation in this case. That condition must pain continuous and severe, with all the resulting changes in the general system which existed.

A word as to the silver wire suture. I have not enumerated it in the list of sutures in this paper, but you will remember I did in my former. I have dropped it altogether. As a buried suture it is a failure. Trouble is afterwards found in many cases—over half—in getting it out, to stop the constant discharge and irritation set up by it. As a superficial suture it is a failure. It is no evidence of weakness, I hope, when I tell you that I was led to use it by no less an authority than the writer of the paper recently read before a certain State Society, on Buried Animal Suture. I was happy in the use of the buried animal suture before I met him, or long before his paper, and am happy to find myself using it since.

Gentlemen, I have been at slight variance with the views I formerly entertained, in two or three particulars; but in the main, my views have not changed since my first operation. And I am just as earnest now as then. My experience has taught me to know that the right road is found, although there may be bad places in it, yet perseverance will enable you to reach the end.

I am sorry to have consumed so much of your time, but I promise not to bore you with a paper soon again. I have endeavored to note those cases that should receive an operation; all cases that are in any way disabled from work or business; that a truss will not readily retain, without pain or inconvenience; all irreducible hernias, or sac, or omentum, where annoyance is felt, and in those others above enumerated. The operation is not dangerous when not complicated with a severe strangulation.

In recent times the mortality following active severe strangulation has been materially lessened; the older statistics placed it at 68 per cent. (Connor). It is yet sufficiently dangerous to avoid; as may be done by a prestrangulated operation in cases where you are led, from above classification, to expect such a result sooner or later.

CLINICAL CONSIDERATIONS CONCERNING ANÆMIA IN YOUNG WOMEN, INCLUDING ITS TREATMENT.[1]

By ANDREW F. CURRIER, M.D.,
NEW YORK CITY.

THIS subject is one which appeals alike to the general practitioner and the specialist. The term *young women* is used to include those who have reached the age of puberty, and the few years which immediately follow it, special stress being laid upon this particular period since every pathologist, and every clinical observer with the most moderate

[1] Read before the Connecticut Medical Society, at its annual meeting in New Haven, May 29, 1890.

powers of observation, does not fail to note the all-important constitutional changes which are inaugurated as puberty is established. It is properly considered one of the critical experiences of life, and as the influences attending its establishment are more or less favorable, so do we see more or fewer complications affecting the general health of the individual. One of the most common complications which presents itself at this period is anæmia, the condition which engages our attention at the present time. The term is a comprehensive one, and includes, in this connection, not merely pallor of the skin and mucous membrane, but a general disturbance of the entire nexus of functions of the body; and though it is generally susceptible of relief, it may be the forerunner of serious or fatal lesions. It is, therefore, a subject which may well command our careful and earnest consideration. Its importance has been impressed upon my own mind by a not inconsiderable experience during the past ten years, both in private and public practice. It has been the custom of some writers, following the lead of Becquerel and Rodier, to consider that form of anæmia known as chlorosis —a form which is more common in young women than in any other class of individuals—as an entirely distinct disease; and Raciborski has attributed it to disorder of the sympathetic nervous system, but without a sufficient basis of fact derived from pathological investigation. It has seemed to me that such a discrimination was not warranted.

[NOTE.—It is not denied that there are cases in which the influence of the ganglionic system in the development of anæmia is very prominent in a causative sense. Such, for example, is the remarkable case published by Dr. W. H. Thomsen,[1] in which the disease was precipitated by exposure to cold and wet while menstruation was in progress.]

With the exception of the greenish discoloration of the skin (and no evidence has been adduced as to the particular origin of this discoloration), the symptoms are the same as in ordinary simple anæmia, and the same plan of treatment which relieves the one will also relieve the other.

Thomas devotes a chapter to the subject,[2] but his arguments lack convincing force, and his admissions only strengthen one in regard to the identity of the two conditions.

Virchow, Perls, Ziegler, and other German pathologists, consider the two conditions as identical.

On the other hand, there are certain conditions which simulate simple anæmia, from which the latter is to be sharply distinguished, and they are the more readily excluded, since they rarely occur at the period of life which we are considering, as may be seen by reference to the statistical tables of H. Müller, Coupland, Eichhorst, and Pye-Smith.[3] Such are pernicious or so-called idiopathic anæmia; Addison's disease, or disease of the supra-renal capsules; Hodgkin's disease, or pseudo-leukæmia; leucocythæmia; scorbutus, and the various cachexias of the chronic wasting or malignant diseases. For a study of these diseases I would refer to the works of Addison, Wilks, Bennett, Biermer, Pepper, Cohnheim, and others, for the literature is extensive.

Anæmia in young women is by no means limited to the rich or comfortable classes, as some writers seem to think. It is common alike among the children of the rich and the poor; those who love and care for their children, and those who are indifferent to them and neglectful of their wants. It may result from over-feeding or under-feeding, from confinement at school, in the house, or the workshop, and with overwork or an absence of work. A noteworthy fact in connection with this disease is its great prevalence during the winter months—that is, during the period in which women and children spend the greater portion of their time within doors. By far the greater number of cases which have been seen by me have occurred at that period of the year, and it has convinced me that herein lies a most important feature in the etiology of anæmia. Vitiated air within is the rule in the winter season, though there is such a wealth of pure air without. It is so in the tenement house, and the palace, the theatre, the church, the school-house, the workshop, and the factory, and terrible penalties are exacted in consequence. It matters little whether the poisonous element be carbon monoxide from imperfect combustion in stoves, furnaces, and leaky flues; carbonic dioxide and organic vapor from the crowding of too many individuals into a given air space; sewer gas from defective plumbing, or gases of decomposition from decaying animal or vegetable matter, from whatever source. The worst feature about poisoning of this character is that it is a continuous process. There may be no offence to the olfactory nerve; or, if there is, the patient soon becomes habituated to it, until she breaks down, or the return of spring compels a supply of pure air through opened doors and windows. In the case of carbon monoxide, which, in my opinion, is the cause of more anæmia—both in young and old—than any other one cause, there is direct combination of the gas with hæmaglobin, which, unfortunately, has greater affinity for this deadly gas than for the life-giving oxygen; and with the defective oxidation of the tissues, and the development of anæmia, there comes also diminished resisting power to disease germs in general.

The winter harvest of disease and death depends upon more than one condition; but you can rest assured that until we can fully appreciate and remedy this defect in the air supply of our dwellings, one of the most powerful causes of disease will continue to act, and all the drugs in the pharmacopœia will not neutralize it. Another important factor in the etiology of anæmia is bad food, by which is meant not only poorly-cooked or mal-assimilable food, but an excess of any one class of proteids to the exclusion of others. With young girls there is very often a great tendency to subsist upon hydro-carbonaceous articles of food, to the exclusion of the albuminoids.

Among the other important causative elements may be mentioned constitutional disease, including scrofula, tuberculosis, and syphilis, malarial poisoning, severe or protracted acute disease occurring as puberty is being established, and including the exanthemata, and disease of the lungs, pleura, heart, and kidneys, insufficient exercise or exhausting labor, and occasionally the various forms of nervous disorders, including chorea, epilepsy, the neuralgias, nervous shock, fear, etc. It may be objected that anæmia is but a symptom in many of these diseases, and this is true; but it is also true that in very many cases this symptom persists long after the original disease has disappeared.

Virchow propounded the theory, based upon post-mortem investigations, that anæmia was due to narrowness of the aorta, or insufficiency in the size of the heart. This may be a satisfactory explanation

[1] Trans. N. Y. State Med. Soc., 1867.
[2] Diseases of Women, Fifth ed., p. 978.
[3] See article Anæmia (J. H. Mussèr) in Wood's Reference Hand-book.

for certain cases, but, as W. H. Thomsen has said,[1] there are so many cases in which it does not apply that it cannot be considered as anything but an exceptional cause. In addition to the foregoing, there are certain conditions, or symptoms, which I have found almost invariably present in every case of anæmia in young women, and which are sometimes to be regarded as cause and sometimes as consequent or concomitant. These relate to the alimentary canal, and are as well marked as anything in the entire morbid situation. They consist in pallor of the mucous membrane of the lips, mouth, and pharynx, flabby condition of the tongue—which is covered with a nasty white fur, gastralgia, fermentative dyspepsia, obstinate constipation, with the occasional discharge of light-colored, pasty stools, and frequent recurrence of painful tympanites. The fæces show a deficiency in the biliary secretion; there is occasionally an aching or soreness in the hepatic region, and the odor of the breath is intolerably offensive.

The functions of the urinary apparatus are usually undisturbed; in fact, I do not recall any case, unconnected with nephritis, in which there was complaint of trouble in this viscus.

Comparative analysis of the urine in a series of cases of anæmia would furnish interesting data as to the variations in albumen, urea, uric acid, and the inorganic constituents; but such investigations, so far as I know, have not been made. Not infrequently there is profuse vaginal catarrh, and this, with the other symptoms pertaining to the genital organs, will be considered in greater detail, for it was these symptoms which brought many of my cases to my notice. The appearance of the skin is characteristic—it is pale, sometimes almost a waxy white; the nails are bloodless, and the extremities constantly cold and clammy. The conjunctival, nasal, and vaginal mucous membranes share in the pallor which characterizes that of the mouth and pharynx. The patients are constantly weak and languid, suffer much with headache, are incapable of any sustained exertion, and are apathetic and indifferent to their surroundings. Œdema of the ankles and eyelids is an occasional, but by no means constant, symptom. It is to be explained by the weakness and low tension of the vascular system in general.

In some cases there is emaciation, in others the subcutaneous fat may be abundant, or even excessive. Usually there is drowsiness, and a desire to sleep the most of the time; but in some cases there is insomnia.

[NOTE.—In a recent clinical lecture upon this subject by my friend, Dr. Thaddeus Reamy, of Cincinnati,[2] in which I have been pleased to find views which corresponded entirely with my own, a case is narrated in which insomnia was a prominent symptom. I think such a symptom is exceptional, however, and not customary.]

The heart action is feeble and rapid, as would be expected, and anæmic murmurs are not uncommon. As a rule, they have no serious significance, and disappear with the return of health. Another symptom which is frequently present, and a source of great disturbance to the mothers of the young patients, is amenorrhœa, or oligomenorrhœa (*i. e.* scanty menstruation), and very rarely polymenorrhœa (profuse menstruation).

If we give the subject a moment's thought we will realize that there is every reason why this symptom should be present. The menstrual flow is the visible evidence of congestion of the pelvic circulation. Menstruation means much more than this, but we need not discuss other considerations at present. If the pressure in the vascular system is low, pelvic congestion will be unlikely to occur, and little or no blood will be discharged, though there may be venous stasis and œdema in certain parts, as we have seen. Anæmia often occurs at the time when menstruation should be established, which, in our climate, varies usually between the twelfth and sixteenth years, and while it persists it is a sufficient explanation for the non-appearance of the menstrual flow. Instead of being regarded as an evil, it should be considered a conservative procedure on the part of nature, for, poor as the blood is, anæmic patients cannot afford to lose much of it, and if the loss were considerable, a very unfavorable complication would be added to the disease, which might modify the prognosis to no inconsiderable extent. Again, an undeveloped condition of the uterus and ovaries is believed by some writers (Perls, Thomas) to be not only the essential cause of the amenorrhœa in these cases, but of the anæmia as well. That such a condition of these organs may be a cause of amenorrhœa is undoubted, though menstruation does not depend entirely upon their integrity and normal development; but it would be difficult to prove that it was a necessary cause of anæmia. There are many cases in which amenorrhœa exists without anæmia. There may be anæmia with co-existing metrorrhagia, as Virchow has shown, and as many others could testify. Still, in a number of cases in which it has seemed to me proper to make a vaginal examination, I have found an undeveloped or deformed condition of the uterus co-existing with anæmia and amenorrhœa. It is not improbable that anæmia existing prior to puberty may so modify the nutrition of the pelvic organs that the establishment of menstruation will be delayed; but we still have much to learn upon this entire subject.

The condition of the blood in anæmia is an important consideration. Its tension in the vessels is lessened, for the central source of power—the heart muscle—being impoverished and weakened, the entire vascular system must suffer in consequence. The color of the blood in anæmic girls is a pale red, and it is watery—that is, hydræmic—in consistency. This means deficiency in red corpuscles, and consequent deficiency in hæmoglobin. If the anæmia is due to the absorption of carbon monoxide, as I believe is frequently the case, this would account for the destruction of the red corpuscles and the combination of this gas with the hæmoglobin.

The white corpuscles are increased in number, for the supply from the lymph ducts continues, however great be the destruction of red corpuscles. Many of the red corpuscles are very small (microcytes), and some are very large (macrocytes), and they may have a crenated or dentated appearance. These changes in the size and shape of the corpuscles have been very fully studied by Hayem, Osler, Mackenzie, Eichhorst, and others. The blood of anæmics also coagulates less readily than that of those who are in health. This would possibly indicate that the fibrinogen of the plasma was diminished, while the paraglobulin and fibrin ferment of the white corpuscles, which are in excess, were normal or superabundant. The albumen of the serum is increased.

The course of simple anæmia depends upon various conditions. With those who have no complicating disease the return of warm weather, when the air supply in the dwelling is improved, means an im-

[1] Wood's Reference Hand-book, article Chlorosis.
[2] See *Journal of the Medical College of Ohio*, May, 1890.

provement in the anæmia. With those who have the taint of inherited disease, the conditions are favorable to its development. With others, the prompt and continuous administration of suitable remedies, and the adoption of proper diet and exercise, will sometimes work wonders, even though the hygienic surroundings continue less favorable than could be desired. My experience has been particularly gratifying in dealing with this condition, and I have rarely failed to see evidences of improvement when the line of treatment which was recommended has been faithfully followed.

In my plan of treatment I have made no distinction between those who were chlorotic and those who were simply anæmic. As already stated, I believe that chlorosis and anæmia are essentially identical.

Prevention is better than cure, and many of the cases of anæmia are entirely preventable by proper attention to air supply, food, and exercise. Of course, this means a reform in house-building and in the habits of our girls which will be little less than revotionary, and I am not sanguine that such a reform will occur. Indeed, until the love of physical beauty has in it something of the passion which inspired the Greek nations—which, in the best days of their prosperity were the most highly cultured people, physically and mentally, the world has ever seen—there will be, in the majority of cases, a disinclination to submit to those irksome regulations by which physical beauty is acquired and retained.

The three legs of the therapeutic tripod, in the treatment of anæmia, are hygiene, diet, and drugs; and all are indispensable.

It matters little what has been the cause of the anæmia, the main requirement is the same for all, namely, improvement in the condition of the vital fluid. If the air supply in the home is imperfect, it must be remedied by improvement in the plumbing, by letting in more sunlight, by better ventilation, by less crowding—that is, more air space per individual—by a change of dwelling, if necessary. If the condition is traceable to an improper school-room or workshop, the girl must be removed from it. This may be difficult or impossible, but nature's demands are imperious, and this may be the only alternative. There should be daily exercise in expanding the lungs to their fullest extent, and that, too, in an atmosphere which is pure and wholesome. In most cases the daily inhalation of pure oxygen, which can now be readily obtained in most of our large cities, will hasten the return to health. Sun-baths and daily exercise by walking or riding must also be insisted upon. Horseback riding, for those who can afford it and are strong enough to bear it, is one of the best means of exercise; but neither this nor any other form of exercise should be too violent, nor carried to the point of great fatigue. With girls who are compelled to work, the work must be made as light as possible, and it would be far better to discontinue it altogether and allow mind and body to vegetate for a time. Sleep must be encouraged; one should go to bed early and get up late, and it would be well to take a nap every afternoon—or, at least, lie upon the couch for an hour. It is well to take a sponge-bath, with moderately cool water, on rising, and follow it with brisk rubbing of the entire body. The diet must be simple and nutritious. Tea, coffee, and alcohol are usually to be avoided, also fresh or badly-baked bread, and rich or indigestible food of all kinds. Albumenoids, in as great quantity as can be readily disposed of, are indicated, especially rare and lean beef and mutton, an occasional soft-boiled egg, and large quantities of milk. The latter, which is everywhere obtainable, is within the means of the poorest and is usually well tolerated, has been with me a mainstay as an article of diet in this disease. If one can succeed in getting a girl to drink two quarts of good milk daily, there is little doubt but that her condition will improve. There can be no question concerning the utility of iron in this disease. It is a component element of hæmoglobin. Hæmoglobin is the medium by which oxygen is distributed to the tissues. In anæmia we have a deficiency of red corpuscles, and consequently of hæmoglobin and oxygen. Iron stimulates the development of red corpuscles, and is indicated above all things else in anæmia. I have ceased experimenting with the various preparations of iron, having found in the combination of the sulphate with the carbonate of potassium, in the pills known as Blaud's pills, a preparation which leaves nothing to be desired from a pharmaceutical stand-point. The praise which was given to this preparation by the late Prof. Niemeyer was not extravagant. I begin treatment with one of these five-grain pills after each meal, quickly increasing it to two pills three times daily. The addition of arsenious acid is frequently beneficial, three to five drops of Fowler's solution after meals being an efficient dose. Almost invariably it will be necessary to relieve constipation, and I have found nothing better for this condition than one or two compound cathartic pills at night, with a saline before breakfast the following morning.

This laxative treatment must be continued, with suitable intermissions, as long as the constipated habit remains. Equally important is the regulation of the digestive function.

If there is fermentative dyspepsia, an occasional dose of salicine, or other suitable antiseptic, may be given before eating, while if the digestive power is feeble, we can afford great relief by means of one of the excellent preparations of pepsin which are now available, with or without the addition of hydrochloric acid. I have also seen great benefit from the use of hot water, a tumblerful being slowly drunk about half an hour before each meal.

I have reserved until the last the very important question as to the propriety of vaginal examinations and local treatment in these cases; and it is a question in which no little judgment and conscientiousness must be exercised. In general, I do not hesitate to say that such examinations should be omitted unless the indications for making them are very clear. If the anæmia with amenorrhœa occurs in one who has previously been in good health, and has menstruated a certain number of times without any particular abnormality, an examination is not indicated until a fair trial has been given to the treatment which has been suggested. I have many times adopted such a course, and have never yet regretted it. If anæmia occurs in one who has never menstruated, the previous health having been good, an examination should be deferred until the restorative treatment has been fairly tried. If the anæmia is relieved, and menstruation fails to appear after a few months, a vaginal examination should be made, presupposing that all the facts indicate sufficient maturity on the part of the patient for the establishment of the menstrual function. If anæmia comes with great disturbance of the menstrual function, and clear indications of disease of the pelvic organs, a vaginal examination is indicated, the same as if anæmia were not present. The age of the patient should not interfere with the performance of what is clearly a duty.

159 East Thirty-seventh Street.

Society Notes.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Special Meeting, June 17, 1890.

J. A. LIPPINCOTT, M.D., President pro tem., in the Chair.

CASE OF SUSPECTED VOLVULUS.

DR. BATTEN reported: On Sunday, June 8, I saw a man who had been suffering for several days with intense abdominal pains. There was sickness at the stomach. I gave him a quarter of a grain morphia sulphate and extract of belladonna every hour. That did not control the pain, and Dr. Pollock was called in consultation. We continued with the belladonna and the sulphate of morphia every hour, and a hypodermic injection of morphia every six hours. This quieted him. The morphia and belladonna were continued steadily, and when the pains became unbearable, morphia was injected. He continued in that way, with vomiting, until Friday. I omitted to say we injected warm water into the bowels. On Friday afternoon there was a passage of the bowels, and we omitted the hypodermic injection and the morphia and belladonna, and gave him Rochelle salts in small doses. Yesterday he had three hours sleep. Last night he slept all night. To-day he is well.

DR. BUCHANAN: I would like to know if any tumor could be felt?

DR. BATTEN: No, but the abdomen was very hard.

DR. LANGE: I would submit that Dr. Batten has given no evidence of intussusception; it might have been a case of ileus, a case of fecal obstruction, or of typhlitis; Dr. Batten has given no evidence of volvulus.

DR. BATTEN: It was an obstruction of the bowels. No hard matter came away after the bowels commenced to move.

DR. HUSELTON: I would be disposed to criticise the treatment. I cannot readily understand why he should resort to purgatives in such a case. Of course the opiates would be all right to allay pain and quiet the bowels. It seems to me that purgatives would hardly be proper in such cases.

CASE OF PUERPERAL CONVULSIONS.

DR. DUFF: About one year ago, I reported a case of puerperal convulsions to this society. I was called to see a young woman of twenty, about two weeks before the time of labor. I found general anasarca as well as urine loaded with albumen, and I treated her, as I indicated in my report, by giving her digitalis. About six days after, I was called to see her. She was taken in convulsions, which could only be controlled by chloroform. These we controlled for about twenty-four hours, when they returned. I then dilated and delivered her of a male child. The child lived about a week. The mother made a good recovery and did not have convulsions after delivery. Against my orders, she cohabited with her husband and became pregnant within three months. Before pregnancy her urine was normal. At four months I examined her and found considerable albumen. I then put her upon nitro-glycerine, one drop doses three times a day, with the result that the albuminuria disappeared. At six months the albumen returned, as well as the dropsical condition. She was again put on nitro-glycerine and there remained a slight trace of albumen during her whole pregnancy. She was confined last Tuesday morning; I applied the forceps, delivered her, and she has made an excellent recovery. I might follow this case with another almost similar in history, in which nitro-glycerine was used with as good results; but in a third case it did no good. Taking it all in all, however, my experience is that nitro glycerine is one of the best remedies we can use in these circumstances.

DR. CONNELL: Two such cases came under my notice. One showed about 10 per cent. albumen; this was at the beginning of the seventh month. In about two weeks I was called to see her in convulsions. Another case was one in which I was called by Dr. Hallock. In this case there was no albumen in the urine. The woman had reached full term and the labor progressed slowly but favorably; being first labor, of course it was a little tedious. During the second stage, she was seized with a terrific convulsion; during the time we were delivering her, which we did as quickly as possible, she had three or four convulsions. There was no trace of albumen in her urine.

DR. STEWART: Albuminuria, uræmia and convulsions during pregnancy are invariably ascribed to circulation interferences by pressure of the enlarged uterus. But it is worthy of note that abdominal tumors as large as the uterus at term, and occupying the same situation, do not entail these results. How can this be explained? It is to be remembered that pregnancy possesses other means to effect convulsions, namely, through the nervous system. In addition, discrimination is necessary, and all convulsions occurring during pregnancy, labor, and the lying-in, are by no means to be ascribed to, and treated as, the result of uræmia.

DR. GREEN: April 28, last, I was summoned to see a child six years of age, with typhoid fever. The patient remained ill with the characteristic temperature curves during twenty days. During the last six days, cerebral symptoms seemed to predominate, and about the time the fever subsided and the temperature became normal, the child seemed to convalesce rapidly, and seemed cheerful. On the twenty-second day, when I called, they told me the child had not spoken the past night, and had spoken but once since I made my visit the day before. She continued in this mute condition for six days without uttering an audible note. During this time there did not seem to be any unusual delirium, but about twenty-four hours before she began to speak she manifested considerable delirium of rather a cheerful nature. It was on the seventh day she began to speak, and within forty-eight hours she talked as usual. I think this case is unusual. The child made a good recovery, and is now apparently as well as before the illness.

DR. BUCHANAN: I have seen a case very similar to Dr. Green's. A child seven years old was attacked by typhoid fever, and passed through a typical course of fever lasting four weeks. The child was then unable to speak. It had no other cerebral symptoms whatever. In all other respects the case was an ordinary one. It returned to speech more gradually than Dr. Green's case, but finally completely recovered. I think it was almost a week from the time it commenced to say individual words until it was able to express its wants.

DR. HUSELTON: I have to report a case of dislocation of the hip-joint. The dislocation was that which is commonly known as the dorsal dislocation. The case had been seen and manipulated by another

surgeon, and in the manipulation the head of the bone had slipped into the thyroid foramen, an accident which may happen to any one of us, and which is not so readily reduced. On my third effort I succeeded in dislodging the bone, and it returned to its place with a snap so loud that I felt certain I had fractured the neck, but was glad to find that I had not. This is the third case of dislocation of the hip I have reduced by manipulation. The first one I had no difficulty with whatever. The second one I also succeeded in reducing without special effort. The patient made a quick recovery in this last case.

DR. MCCANN: This is not an uncommon accident in attempting to reduce a dislocation of the hip joint; in the effort to place the head of the bone in its normal position, unless there be extreme care exercised, it will be thrown into one of the other dislocations. Some years ago a man was struck on the back by a railway train, and sustained a dislocation of the hip, as well as other injuries. When he was brought into the hospital it was not appreciated that he was fatally injured, and an effort was made to reduce the dislocation. The effort most signally failed for a long time; finally the bone slipped into position just as the man was dying.

A post-mortem showed that not alone the fibro-cartilage around the periphery of the acetabulum, but a bony section at the superior edge also was fractured off. The specimen was not retained. It would have been of value. A few years ago a child of ten years was subjected to several efforts at reduction of the dislocation by manipulation. The head of the bone could be thrown into the thyroid foramen, and was apparently reduced, but as soon as the extension was removed there was an immediate reproduction of the dislocation, although a deformity did not exist. After two or three surgeons had made a number of efforts to reduce the dislocation by manipulation, the child was put in bed with extension by a splint, and eventually recovered. I am satisfied that this case—although, fortunately for the child, we had no opportunity to verify the opinion, for she lived—was also a case in which the cartilage, and perhaps some bone, had been torn off.

Occasionally, as has been demonstrated by Dr. Murdoch, dislocation which cannot be reduced by the ordinary manipulations will be reduced by a little traction. I remember one in which I was able, by my own unaided effort, catching the foot and pulling powerfully upon the limb, to replace the head of the bone in the socket.

DR. PETTIT: Two cases I saw in the hospital which were reduced by extension. One had been worked with a long time by a half dozen physicians and attendants, and there was failure to reduce the dislocation. While they were rigging up the rope and pulley arrangement to try, some one grasped the man by the limb, and by no great force, but simply by steady pulling for maybe three-fourths of a minute, the bone slipped into place. Since that time I have seen one other case reduced in the same manner after quite a good deal of manipulation without success, by extension without a great deal of force, but the force being kept up some minutes steadily.

DR. BUCHANAN: I recall a case in which efforts were made to reduce a dislocation of the hip in a railroad man by, I suppose, five or six competent surgeons, and, when they were through, the reduction was unaccomplished, and the opinion was expressed that it must be a fracture of the rim of the acetabulum neck, and that it was impossible to reduce it. Dr. LeMoyne requested to be permitted to put on an extension, and by extension and some little manipulation—not the ordinary manipulation, but manipulation during extension—he reduced this hip-joint. This man was on the point of being returned to bed with his luxation unreduced when the successful attempt was made.

DR. BATTEN: I had a case of dislocation of the hip, and could not reduce it. Dr. Emmerling, Dr. Dickson, and Dr. Reiter were present. The bone went into place with a snap under Dr. Reiter's manipulation.

DR. KŒNIG: I would like to ask if it might not be possible that the position of the rent in the capsule has much to do with the return of the bone—where the surgeon is not able to return the bone by the method of manipulation, and where the method of extension is readily followed by reduction of the bone, is not the location of the rent a factor in the case?

DR. MCCANN: What I wish to say is that, in the cases of extension, the patient being entirely under the influence of an anæsthetic, completely relaxed, the amount of force used was not great. In my own cases I did not exert a very great force, and it slipped in.

Another method consists in etherizing the patient, laying him on his abdomen on a table, and allowing the limb to hang down over the end of the table. The result is that, after a certain length of time, the muscles of the abdomen relax, and with almost no manipulation the head of the bone is thrown into its proper position.

DR. HUSELTON: A farmer sustained a simple dislocation of the shoulder. He was taken into the town of Harmony, where two surgeons tried to reduce the dislocation. They failed, and had the man loaded into a spring wagon and sent to my office, with a note asking me to call in some of my friends and attempt to reduce the dislocation, and, in the event of a failure, to send him to the West Penn Hospital. I said I would make an attempt to reduce it myself. I took the patient into my back office, laid him upon the lounge, and, standing behind him, I pulled and told him to pull, which he did; and I think the dislocation was reduced in about two minutes. Now these were competent men who failed with this case, and they seemed to have exhausted every effort. Therefore I think we should be very charitable indeed before we condemn a physician for failure to reduce a dislocation.

THREE CASES OF FATAL PERICARDITIS—WITH AUTOPSIES IN TWO.

DR. LANGE: I wish to report three fatal cases of pericarditis. The first was a large German, previously healthy, with no discoverable hereditary taint except that his mother had died of some lung disease at the age of thirty-two. The man was a cooper by occupation, and boasted of his previous excellent health. He presented, on examination, the usual signs of pericarditis except that of pain. He presented, in addition, the ordinary signs and symptoms of a slight fever. Pericarditis was suspected in this case, and, during the next three weeks under observation, it was ascertained to exist. This man died, of heart failure, on the water closet. The autopsy showed the heart to be the so called hairy heart. There were numerous and strong adhesions between the parietal and visceral layers. Other lesions consisting of organized bands from the visceral to the parietal pericardium of from a quarter to an inch in length, and as strong as the chordæ tendinæ. These

must have exerted a potent and pernicious influence upon the contraction and rotation of the organ. Still other bands were free at one extremity, which floated in the very limited amount of effusion. This was a tubercular pericarditis ; and nowhere else throughout the body was tubercle discovered.

The second case occurred in an Italian, aged thirty-five, who had a left-sided, lower-lobed, croupous pneumonia, accompanied by a pleuritic effusion large enough to require tapping. In the third week, resolution not happening, the pneumonia became purulent, and thus developed the secondary pericarditis. On autopsy, the heart was found to be like the first, and the effusion to be small. The patient died while sitting on the edge of his bed.

The third case was an Irishman, a very active man, yardmaster at one of the railroads here. He came to my office complaining of shortness of breath and presented the signs, symptoms and phenomena of a mild fever. He had no pain, little headache, little backache, general malaise, anorexia, in short all the signs and symptoms of a slight fever, a pericardiac friction murmur, and a tumbling heart, but no en larged area of cardiac dullness. Dyspnœa was his only complaint. He had it two months and it was growing. After two weeks he thought himself so well that we could not restrain him. He would leave his bed and go about his room. One Sunday morning he sent for a barber to shave him. He got up, sat on a chair, took the Sunday paper to look it over and fell dead. There was no post-mortem. From repeated physical examinations I be ieve the condi tions would have been found as in the other cases. In pericarditis of gravity, which cases constitute the small minority, there is one remedy to which we at last arrive. This is digitalis. It is said that digitalis is proper to strengthen the action of the heart. My experience with these cases and others leads me to think that digitalis has very little effect in increasing the power of the heart in pericarditis. Another point is that death from pericarditis, which is usually ascribed to the size of the effusion when it is large, may be due rather to interference with the action of the heart by adhesion. It is my opinion that this latter is frequently, and that large effusions are rarely, the cause of death. Large effusions belong rather to those inflammations of the pericardium which complicate rheumatism and nephritis, and which are not fatal. When the effusion is large, what can we expect from digitalis? The interference in this case is not with contraction—but with the filling—the diastole of the heart; and this being purely a muscular relaxation is uninfluenced by digitalis. The only effect then that we should expect is that which would happen after the administration of digitalis, in, for instance, the granular degeneration of typhoid fever, pneumonia, or any disease of gravity and duration ; and this, it must be confessed, is little. The effect, indeed, would be less, for even if the systole should be improved by digitalis, the diasole cannot be, and consequently the intra-arterial tension is not increased. On the other hand, if the adhesions constitute the obstacle to efficient contractions, we can understand how an increase of power in systole by digitalis might fracture, tear off, or free the parietal from the visceral pericardium, and thus allow an increased quantity of blood in the arterial system. But I have not observed this to happen, and the administration of digitalis for pericarditis is pregnant with disappointment, and is in striking contrast with its effects in heart dilatation.

The Polyclinic.

PHILADELPHIA HOSPITAL.

ULCERATION—SKIN-GRAFTING.

THE deeper structures of the body are separated from the air by a membrane—the skin—upon which is a growth of epithelial cells. When the epithelium is disturbed, an irritation is the result, and from this irritation come different reactions that will produce a certain amount of destruction, and then disintegration of tissue with slough, and we have left an ulceration. An ulcer is a solution of the continuity of the soft parts that has been contaminated by some micro-organisms, which find here a suitable soil for their development and growth. These micro-organisms irritate the surface, forming a substance called the *ptomaine.*

You all know that beer is due to the growth of a germ in a sweet solution ; and, because the germ has grown, that sweet soil has changed its nature, and becomes what we know as alcohol. So also, in an abrasion of the skin, we have the serum of the blood, which is an albuminous and harmless fluid ; but, when germs grow in it, it is no longer serum, but is disintegrated and acts as an irritant, and ulceration is the result.

Let us examine for a moment a section of the skin with a microscope, and what do we find ? The upper or outer layer is the epidermis, which is composed of epithelial cells arranged in layers, and dipping down into the depressions between the papillæ of the true skin. Below the epidermis is a basement or limiting membrane, which separates the papillæ from the epithelial layers. The papillæ and true skin lie beneath this basement membrane, and each papilla is freely supplied with glands, nerves, capillaries, vessels, and hair follicles. Below this is fibrous connective tissue.

In an ulcer the mouths of the vessel are open, and, as a result of the irritation, there is a congestion, and the white corpuscles of the blood escape from the open vessels, and illustrate a phenomena called *diapedesis* (I travel through.)

A white corpuscle, from the time it has left the vessel, is a granulation-cell, and is an integral part of the surface of rosy granulations, and this is the reason we have a healthy sore. This would be the case and would remain so, if it were not that something destroys these granulations, and that something is a germ. The germ causes death of the cell, and, as a result of its death, we have what is known as *pus.* When you see a pus-corpuscle, it expresses the failure of a cell to be formed into tissue.

Suppose this has not been the case, and antiseptic agents have been used to prevent the micro-organisms from getting into the parts—the cell is allowed to perform its function, what happens?

At first the cell is round ; it elongates and assumes the spindle shape, and finally forms a fibrous cell, and enters into the formation of tissue. In this way the ulcer fills with cells to the surface, and in time these granulation cells form a dense mass of fibrous tissue. Below are the fully developed cells, while on the surface we find the younger cells. When the ulcer has filled to the same level as the epithelial layer, all that is required to complete the healing process is to cover it with epithelium, and we have a true healed sore. How do we get this epithelium ?

It can be obtained slowly or quickly. If you desire to wait, that epithelium can grow only from the sides of the ulcer by proliferation, and in several months

the cells will spread from the sides and cover it. But when you have to deal with a large ulcer, you cannot wait for this.

Reverdin taught us the *grafting* process by taking epithelium from the body and placing it on the ulcer. He took small bits of epithelium and implanted them over the ulcer; but this was a slow process. Following out the same theory, Thiersch brought it down to this: if you can transplant small amounts of epithelium, what is the objection to transplanting a large amount?" He simply cleanses a portion of the body and renders it aseptic, and peels off strips of epithelium in a sawing way, as you would peel a potato, and covers the ulcer entirely, and, if you have been aseptic, union will follow and heal completely.

You will find that the cases are selected, as it would be a vain endeavor to transplant epithelium upon a soil that is unsuited to its growth. The surface of the ulcer must be prepared.

First of all, see that the ulcer is filled to the surface with healthy granulations. Sterilize the surface with some antiseptic solution, so that, when the epithelium is put on, pus will not develop. The place from which you take the epithelium must be washed with ether and sterilized—that is, washed with acid sublimate solution.

In this old man before you there is a small ulcerated surface that I think can be covered with two grafts at most. An ordinary straight scalpel is taken, and a graft, three inches long by three-quarters of an inch wide is taken off and the ulcer covered with it. Spread the pieces carefully on the surface to cover the whole sore.

It does not matter if the graft is a little too large, for there will be a small amount of melting, as it were, and the mucous layer takes to the granulations; but the epidermis above is dead, and scales off like dandruff. By making the skin tense in removing the strips you lessen the pain to the patient, for no anæsthetic is required in this operation. The ulcer will then be dressed with sterilized gauze, and the dressing allowed to remain for three weeks. I might have dressed this ulcer with iodoform; but this man has a peculiar idiosyncrasy against it. What should be our guide in the subsequent treatment of such a case? Simply temperature and pain. Where there is no pain, leave the dressing on indefinitely, for the wound is doing well. What have I done in grafting this case?

I have tried to cut the very tip ends of the papillary layer, and I know I have cut them; for, if not, I would not have drawn any blood. Having cut the papillæ, you have gaping mouths of the vessels, which inosculate or anastomose with the gaping mouths of the vessels of the ulcer, and in this way obtain a true union. Eventually, when the sore is well, you will have this difference in the new skin from the surrounding skin: the absence of hair follicles, sebaceous and sweat glands, for you have not cut deep enough to obtain these structures.

What is true for this ulcer is true for all other ulcerations, such as those from burns or plastic ulcerations about the face or other parts of the body. Absolute cleanliness and antiseptic measures may seem to be a light matter; but it is better to be over careful than not careful enough in preventing the contamination of the ulcer with germs present in the air and surrounding media. As there must be some secretion from the ulcer, I will place absorbent cotton over the gauze dressing, to catch it and retain it in a healthy condition.

The healed ulcer will always have a weak skin, and it will tend to return in the same spot, and it is well to wear a compress bandage to support the parts.

[NOTE.—Three cases were thus treated before the clinic, and the dressing removed twenty-one days afterwards. The ulcers had completely healed under *one* dressing.]—*Laplace.*

CIRCUMCISION.

I will bring before you another case upon which I wish to perform the modified operation of circumcision. The indication for this operation is an irreducible prepuce, phimosis, or the existence of a venereal ulceration which cannot be reached when the glans is covered.

Von Bergman, of Berlin, has modified the operation of circumcision. His method consists in slitting up the prepuce over the glans, and trimming the two "dog eared" flaps according to the necessities of the case. No set rule can be followed for doing surgical operations, and a *set* rule is always contra-indicated. You must understand the principle and add any modification that the case may demand.

The man before you has chancroid posthitis and phimosis. We simply slit up the prepuce on the back of the glans; resect the "dog ears;" use a continuous suture of black silk, and stitch the skin and mucous surface together, and the operation is complete. He will have a prepuce left that will cover the glans.

This wound will be contaminated with the chancroidal poison. Chancroid is auto-inoculable, and one case is on record where one man was inoculated two thousand seven hundred times with true chancroid. This man will be given the benefit of the best antiseptic treatment: the acid sublimate solution. Acids will prevent the spread of a chancroid; hence the propriety of using the acid bichloride of mercury locally for a few days.—*Laplace.*

PYÆMIC ABSCESSES.

This woman, whose temperature chart is longer than herself, has been in the clinic a number of times before, suffering with a pyæmic abscess under the knee, that is now healed. The knee is so stiff that she is unable to walk. She has a fair appetite, and is now a well woman. This case illustrates to you that a dangerous case of pyæmic infection during labor may recover. We attribute her recovery to several things, not the least of which is the patient herself, as she had so much courage, and at no time did she give up. The treatment was stimulating from the first; all pus was evacuated just as soon as possible after it was detected. I think she has now recovered sufficiently that she will not need to come to the clinic again. It is now seven months since she was first taken ill. There is no reason why she should not continue to improve indefinitely.—*Davis.*

PUERPERAL DIPHTHERIA.

The next case is one of the same sort as the last one, and she is able to come to the clinic herself, in place of being carried here. She is a colored woman, and came into the house three months ago with a history of being delivered outside of the hospital amidst very bad hygienic surroundings. Examination revealed a severe diphtheritic septic infection from a diphtheritic ulcer on one side of the cervix uteri. The patient's baby became infected with septicæmia from the mother's milk, and died. The glands in the groin of the woman, on the side corresponding to the ulcer on the cervix, were enlarged, and were poulticed with linseed meal mixed

with water, which contained 2½ per cent. of carbolic acid. The diphtheritic ulcer was cleansed and carbolic acid and iodine, with iodoform, was used on it. The patient was stimulated and steadily improved, until she is now almost entirely well and able to appear before us without assistance.—*Davis.*

CEPHALO-HÆMATOMA.

I have here a case of cephalo-hæmatoma that is not recovering as it should. I will have the resident physician extract some fluid by an antisepticised needle of an aspirator, and will then use compression. The temperature of this child has never been above 100° F. It has been wearing a cap with a boric acid dressing over the tumor. The needle is small and nothing but bloody serum is coming from it. Only a few drachms will be removed, and this will amount to one-half the fluid in the tumor. Why not remove all the fluid at once? Because you do not want to lessen the pressure entirely from the walls of the tumor. If you are ever called in to see a man who cannot pass his water, and in whom the bladder is full, you must be extremely careful how you remove the fluid. When there has been long-continued cystitis and occlusion of the urethra, do not empty the bladder completely, for you will so derange the mechanics and physics of the urinary apparatus that you will cause blood to extravisate into the glomeruli of the kidneys and cause trouble. Take about one pint of urine out and inject a solution of boric acid. This analogy holds good in the case of this tumor, and also accounts for the benefit of injecting iodoform, ether, and oil into abscess cavities when pus has been drawn off.—*Davis.*

VITALITY OF CHILDHOOD.

This child came to the hospital on July 14, 1889, and is one of twins. Its mother is markedly tuberculous. This child has survived more dangers and complications than any child I have seen for a long time. It has had measles, bronchitis, gastro-intestinal catarrh, and furuncles. You see that a child may survive the ordinary complications of childhood in a large hospital and still live. It has had a diet of 1 part milk to 14 of water. At times we were compelled to resort to the use of barley water and alcohol. It has had little medication, but has been carefully watched. Every day it lives now is that much more in its favor for a long life.—*Davis.*

PYÆMIC INFECTION.

The next patient is a colored woman who is suffering with a trouble that some call septic and others rheumatic. The patient came in with a history of fever, pain, and malaise after labor. An abscess formed over the sacrum, which gave rise to fistulous tracks. We connected these by incisions and drained by means of soft drainage. Following this the temperature fell. Tenderness began to develop in the left elbow and wrist, with a slight rise of temperature, without a chill. The question naturally presented itself, is it puerperal pyæmia or rheumatism occurring in the puerperal state? I know of no absolute means of diagnosis. If we were to aspirate the joints, take a small amount of the fluid and make cultivations, we may arrive at a diagnosis. She is improving on anti-pyæmic treatment, and the abscess tracks have now healed, and she is gaining in weight. The joints have been enveloped in cotton. Salicylate of soda is a valuable remedy both for rheumatism and pyæmic infection; but we cannot be sure of the trouble that she has if it is given. The main point is to give alcoholic stimulants. I believe this case to be one of mild pyæmic infection.—*Davis.*

NURSING-BOTTLE.

Here is one of those nursing-bottles that comes in from the city. Nothing could be a more efficient breeder of micro organisms than this long rubber tube connected with the bottle. I show it simply for the purpose of condemning it. No child should nurse a bottle unless under observation; and when the meal is done the bottle should be removed. This habit can soon be taught the child. The great objection to letting the child have the bottle all the time is that it fills its stomach with wind from an empty or a half-filled bottle. Use nothing but a small rubber cap on the bottle that can be reversed and thoroughly cleansed.—*Davis.*

PAROTITIS.

We have an epidemic of parotitis in the puerperal wards. Parotitis during pregnancy may be uni- or bi lateral. All the cases were isolated at once—twelve or fifteen pregnant women — and treated symptomatically. Parotid abscess should put us on our guard against puerperal sepsis. Otherwise the mumps have given nothing more than trifling discomfort to the patients. So far as treatment goes, do not make any application that will affect the skin. Keep the bowels free; give liquid diet and symptomatic treatment. If abscesses should form, evacuate them at once freely with antiseptic precautions. Use the acid test as a means of diagnosing parotitis.

—*Davis.*

SAPRÆMIA.

This is a case of fever coming on two or three days after delivery. This woman was brought to the hospital after labor and was allowed to walk upstairs to her ward, and soon after manifested symptoms of fever. No cause could be found to which the fever could be referred. There was no tenderness over the abdomen, and no vomiting. At the present time there is no reason to account for the fever, unless it came from transportation and the exertion in walking upstairs. Temperature was 104° F.; skin fairly moist, and high pulse. I explain it thus: The muscular movements in the upright position have resulted in the absorption of a fibrin ferment that has formed in the mouths of the uterine sinuses, and this set up the fever. We know that absorption of bloody serum after abdominal operations will cause a marked rise of temperature. Careful antiseptic treatment with stimulation is all that is necessary. Now that we are so careful in all our operations and deliveries of women, we have nearly overcome this trouble.

—*Davis.*

CHARLES MARCHAND has issued a pamphlet giving the therapeutic applications of peroxide of hydrogen and glycozone in the treatment of diseases caused by bacteria. Peroxide of hydrogen has been pronounced by Dr. E. R. Squibb to be perhaps the most powerful of all antiseptics and disinfectants. Its harmless character and the absence of all unpleasant taste and odor render it an ideal germicide for use with children.

It appears to us that this substance deserves a much more general trial than it has as yet received; and to those who desire to know more of it we commend the pamphlet before us, which may be procured on application to Mr. Marchand.

CALIFORNIA SANITARIA.

DR. WINSLOW ANDERSON has given us a useful work, in which he has collected a great deal of information concerning the health resorts of California. With the aid of this book, the physician who contemplates sending patients to the Pacific Coast can intelligently advise them as to where to go.

We need just such a book for Pennsylvania; where we have many valuable mineral springs, mountain retreats, lakes, pine forests, and other places specially designed by nature for sanitaria, but which are allowed to remain in obscurity for the want of trustworthy information concerning them and business enterprise to put their merits before the public. Some years ago the State Medical Society investigated this subject, but its report is buried among the proceedings, instead of being published in such a shape as to bring it into the hands of the public. And each summer thousands of our citizens go off to the seashore to contract malaria, enrich Jersey doctors and feed Jersey mosquitoes, when in our own State they could find resorts which are healthier, cooler, very much less expensive, and better-fitted for three-fourths of the invalids than the sea-shore. Somehow, the sea has got the popular fancy, and the mountain must wait for its innings until a change occurs. The majority of pulmonary complaints are, however, best treated by mountain air; hemorrhagic affections become dangerous at the sea-side; anemic conditions in general, and insomnia in particular, do best in elevated regions. For more than half of those who leave their homes in quest of health, the mountains are preferable to the shore; and for those to whom the choice is not material from the standpoint of health, the cheapness of the inland locations renders them most suitable.

But questions of suitability and cost are of really little import in attracting the masses. It is not the best located resort but the best advertised that wins the most patronage. Take Waukesha for instance. A comparatively flat and uninteresting tract, from which arises a number of springs. The waters contain about as much of mineral ingredients as any ordinary spring water; and of no special value.

Twelve grains calcium carbonate, seven of magnesium carbonate, less than one each of sodium carbonate and sulphate, potassium sulphate and silica, a bit of iron, just enough to spoil the water for plethora, a grain of common salt, and nearly two grains of organic matter to the gallon, make up the famous Bethesda Water of Waukesha. The only element of importance is the organic matter, and this is not specially conducive to health. Its presence is easily accounted for. The town lies on a gravelly soil, through which sewerage percolates with little alteration. There is no drainage in the town; and a walk in the early morning affords abundant proof of the purgative qualities of the water, and of the absence of sanitary conveniences. There is only the slightest possibility of any remedial effect being derived from the use of these waters; and until the town institutes a system of drainage, the water should be condemned. And yet the liberal use of printer's ink has sold enormous quantities of this water, and last summer drew over five thousand persons to the hotels of Waukesha. And in full accord with this is it, that none of the other Waukesha springs are as impure as the Bethesda; some of them having scarcely a trace of organic matter; yet as they are not advertised so extensively, they are scarcely known. Those situated on the outskirts of the present town are as yet quite pure; but it is only a matter of time, as the town spreads, when they will become as impure as the Bethesda.

The water from the Katalysine Spring, at Gettysburg, Pa., comes somewhat near the Bethesda in the quantity and nature of its mineral contents; with about one-third the quantity of organic matter, and the addition of borax, barium, lithium, strontium, nickel, cobalt and copper, in traces. Any good to be derived from the Bethesda can be equally obtained from the Gettysburg water, which is of greater purity. Annexed will be found the analysis of these springs in full, for comparison:

THE first annual report of the Southwestern Dispensary, in Bethany Sunday-school building, Twenty-second and Bainbridge streets, for the year ending July 1st, shows that 1,150 medical, 1,107 eye, 136 surgical, 242 gynæcological, and 279 throat, nose and ear cases were treated, a total of 2,914 cases. The physicians' staff consisted of Drs. A. E. Roussel, H. J. Hansell, J. H. Bell, A. Hewson, I. H. Elder, and G. H. Macuen.

Annotations.

APOPLEXY.

THIS is coming to be a frequent means of man's "taking off." In 1885 there were 1,003 deaths by it in Massachusetts, which brings it forward on the list of causes to the eleventh or twelfth for that year, a larger proportion than ever before.

In 1860 the deaths by this disease were 1.93 per 10,000 persons living; in 1870, 2.70; in 1880, 4.19; and in 1885, 5.12 per 10,000.

The two principal conditions favoring the rupture of the brain vessels are the degeneration of their coats and the increased pressure within them. Of the causes of degeneration, the chief by far is the habit of alcoholisms. The pressure is increased by increase of corpulency, which forces the blood into the vesels of the head without increasing their surrounding support, as is the case everywhere else in the body. To this corpulency full living, with less muscular labor among our people, largely contributes. Herein is suggested the proper remedy.

LONGEVITY.

DR. T. VENNER (1638), in the "Correct Way to a Long Life; or, a plain, Philosophical Demonstration of the Nature, Faculties, and Effects of all such things as by way of nourishments make for the preservation of health, with divers necessary dieteticall observations; as also of the true use and effects of Sleep, Exercise, Excretions and Perturbations, with just applications to every age, constitution of body, and time of yeere," says: "To procure vomiting, urine and sweat by meanes of drunken nesse, as it is wicked, so it is also beastly. Moreover, by a remedie of kind, the hurt is farre greater than the help; for drunkennesse, besides that it doth extinguish the light of the understanding, causeth the Apoplexie and such other like diseases of the braine, and often a sudden suffocation. In a word, it doth by much more hurt all the parts and faculties of the body than any way help by evacuation of superfluities, as the barbarous Authors pretend for their assertion; for infinite are the hurts that drunkennesse bringeth unto man's body."

Letters to the Editor.

LETTER FROM DR. GARRETSON.

AS a continuation of my letter of last week, I have to tell you that the name of the third hotel is discovered to be the "Social." The landlord, as some one has told me, came down here six years ago, to die of Bright's disease, or of some other "dis" that was interfering with a state of desirable "ease;" but so antidotal has the salt-laden air proved that he has *gone about*—that, I believe, is the nautical phrase—and has trimmed his sail for the other direction.

A cool looking house with a wide porch about it, painted of a color to agree with a cedar grove in which it is set down, is, under any circumstance, a refreshing kind of an oasis to come across; but when one is half-sizzled and fried from a morning spent in an unshaded boat upon an inlet, and when, added to this, he is parched out by thirst, and wilted by reason of not having had a mouthful to eat since four o'clock in the morning, the oasis is found a something for which an appreciative man thanks the gods.

There is, in the case of this particular oasis, another "but." Mr. Kroger—this is the landlord's name—is an entirely dependable-upon man, as regards a glass of cool Rochester, or, better than this perhaps, a cold looking, dust-covered bottle, with promise within it of Egg Harbor's famous Iolink, or Franklin, '73. This good man is no sciolist in the direction of his business. He knows just when to ice, and when and where frigidity is out of place. He knows better than yourself what it is that is to meet the indication.

Doctors are partial to billiards. The sanded room led to by the porch among the cedars furnishes a good table. It furnishes more than this; the blue fish and sheepshead stories are something only a little less than fabulous; while recitals as to wrecks upon this wild Barnegat coast—these not at all intensified or drawn out—cause you to look with admiration and profound respect upon the actors in them, as these stroll in and out and are pointed out to you.

From the stories, one goes naturally to look at the life-saving station. This is a convenient building, furnished with the necessary appliances, having its location directly at a point on the coast where an endless line of angry-looking breakers impress the beholder as being on the lookout for luckless ships. A more responsible, more dangerous, or a poorer paid situation is not to be imagined than this occupied by Captain Ridgway and his heroic men. To get out of bed at midnight, and to take to an open boat amid ice and driving waves and blackness, is something to put ordinary courage into a childish comparison. Last winter three of these noble men lost their lives.

The oldest inhabitant has become to everybody "Uncle Parker." He typifies the "lone fisherman," or the lone fisherman typifies him. Uncle Parker has a real fisherman's home at the side of a sand hill that separates Barnegat's famous flash light-house from the inlet. There, summer and winter, he has lived for thirty years, spending the one season in hooking sheephead, the other in shooting duck. It seems to be a lonely life, but the old man evidently enjoys it, as do a dozen or sixteen cats which are always about him, or in his lap when the "evening pipe is lighted." A good wife shares his discomforts and doubles his comforts.

The principal men of the place—being everybody's friend, and everybody being their friend—are Mr. Boice, proprietor of the Oceanic Hotel, and Mr. Butterworth, the postmaster and general merchant of the locality. These two gentlemen seem to have, as the meaning of their lives, the making of everybody comfortable. The Oceanic is a hotel numbering two hundred rooms. It is not at all the place to go to if dissipation, rather than health, is the object. The house is one of rambling architecture and proportion. The piazzas are broad and long, and take in a sight of everywhere. There is an entire absence of wearisome formality, but there is no want of that refinement which is the comfort of a gentleman's home.

The store and post-office is the place where everybody goes every day. A board walk leads from it in one direction to the beach, and in another to the hotels and cottages. Here one finds about everything one needs. Mr. Butterworth knows all about fishing lines, and is never without one to lend to the latest comer. He knows, too, about everything you may want to know as regards the whole Barnegat coast. Better even than these, he is a man who makes you feel that in troubling him you confer a

pleasure. If you, or any of your readers, come to this place, be sure and make the acquaintance of Mr. Boice and the postmaster.

"Are there any green-headed flies?" queries one of the readers of THE TIMES AND REGISTER through a letter.

Some.

Another of your subscribers asks about "mosquitoes."

Some, also.

"Is not the ride to Barnegat a long and dusty one?" inquires still a third, whose letter bears the Germantown postmark.

It takes two hours and a half to reach here from Philadelphia. If one cannot afford a dollar duster, a good time to come is after there has been a shower.

One asks what kind of a place it would be for a half dozen young doctors to club together and come to.

I would recommend it warmly. There are several small cottages furnished, and ready for such a company, that can be rented for a song. The bay will furnish the kind of food said to be good for making brains—a matter worthy of consideration by all of us who are of the cloth.

I am to give myself six weeks here. Three are already gone; although it seems to me that my flannel shirt took the place of my ironed one only yesterday. I do not know how my physician will esteem me to be looking when I get back to town; but I feel like cast iron—metaphorically.

BARNEGAT CITY, ON THE BEACH AROUND THE BLUFF.

INJURY TO NOSES.

THE following item in a daily paper attracted our attention, and a note to Dr. Saunders brought this description of a very interesting case:

"During a baseball game at Scranton, Ia., the other day, Everett Phillips was accidentally struck in the face with a bat, completely flattening his nose. The doctor pulled the member back into position, placed a tin cornucopia over it to keep it in form, and Everett is now known among his fellows as 'the man with the tin-nose.'"

The newspaper report is badly exaggerated. Young Phillips was struck with a *ball* on the right side of the nose, causing displacement of both nasal bones to the left. The articulation of each nasal bone with its fellow was intact, but disarticulation had obtained at every other point. Lateral pressure on left nasal bone rectified matters, and reduction was maintained by a strip of tin bent at the end, so that it did not slip when traction was made upon it; this was caught or placed over left side of nose, brought upward and outward over opposite brow, then well around the head, and kept in place by a roller bandage. The dressing was necessarily somewhat inconvenient, which hastened its removal in twenty four hours, but left a good result.

I wish this could have been of as much interest as the clipping has made it.

WM. J. SAUNDERS, M. D.

SCRANTON, IOWA.

OCEAN CITY.

IT pleased me much to read amongst your "Notes and Items" the fact that Drs. Kynett and Thatcher are at Ocean City.

Ocean City is a quiet summer-resort, just the place for a physician to enjoy himself. The bathing is far superior to that of Cape May or Atlantic City; and the sailing is spoken of by all as "grand." Crabbing, fishing, and gunning are much enjoyed by the "sports" of the profession could hear of this lovely resort. Once having visited it, they would continue to do so year after year. I am one who has visited Ocean City every summer for years.

WM. L. ROBINS, M.D.,
Resident Physician.

Hospital of the Good Samaritan,
BALTIMORE, MD.

CORRECTION.

PERMIT me to call your attention to the fact that your *retention* of the modern languages, French, German and Scandinavian, as *alternates* for the Latin, on page 564, is not correct.

You publish it just as the Committee reported it for the action of the College Convention. But, after considerable discussion by the Convention, all languages were stricken out except the *Latin*. Consequently, the Secretary's notices, in the *Boston Journal* and elsewhere, are correct. N. S. DAVIS.

CHICAGO, ILL.

QUERY.

WHAT per cent. of ruptured perineums is caused by the passing of the shoulders? Will some physician answer through this journal?

Paris Letter.

THE ACTION OF TESTICULAR LIQUIDS.

PROF. BROWN-SÉQUARD returns again to this subject, which he introduced a year ago to the attention of the Société de Biologie. We said at the time, that whatever Dr. Brown-Séquard proposed, deserved, at least, the serious consideration of scientific men, as his great merits as a physiologist commanded attention, no matter what the first impression was in regard to the matter at present in discussion. Dr. Brown-Séquard, in his present communication, very justly complains that he had been the subject of constant attacks, not only on the part of the daily press, (for whose opinion he does not care), but also in the scientific journals, who should, he says, discuss seriously the researches that he is making, which have no other end in view but to elucidate an important biological problem. These studies the doctor has continued, and they have been continued by others, and we shall try to give a short account of the results obtained: First of all, Brown-Séquard only said that when he made his first injections on himself, he saw a considerable augmentation in power in the flow of urine, and a regularity in defecation. With this, he noticed an increase of muscular force and a facility in doing intellectual work that was greater than it had been for years before. *This is all that he claimed.* The rest was the absurd exaggeration of newspapers.

After the first injections Dr. Brown-Séquard made on himself, he went to England for a while, and on his return here, during the past winter, he was taken ill with a cold, and went to Nice, to pass the worst of the bad weather, during all this he did not make any injections, but finding now that his health was not good he resolved to try them again; he, however, could not do this under the strict rules as to asepsia that he always surrounds himself with in his Paris laboratory, and, therefore, he thought of another

method, which would prevent the dangers of subcutaneous injections, which was *rectal injections*. The results obtained were just as complete and as satisfactory as by the hypodermic method. The injections must be well diluted and the quantity of testicular fluid employed must be greater, but the results are just as good. There is no danger of complications, unless the liquids are used too concentrated, when a slight irritation may be created. He injected, each time, the liquid obtained from the trituration of two testicles of guinea-pigs, diluted in fifty centigrammes (cubic) of water. That of other animals can be used (rabbits, dogs, sheep, or calves, etc.). Dr. Brown-Séquard again asserted that the effects produced on him were as stated, but he preferred to give the results of others' work. Leaving aside the rash and foolish attempts of all sorts of people, he only spoke of scientific men who tried it properly. In certain cases of cachexia from malarial fevers its results were wonderful, in others of ataxia locomotrice the amelioration had been remarkable in some cases, while in others no results had been obtained. Good effects were obtained in certain hemiplegias, consecutive to cerebral lesions. In certain dyspepsias, and in cases of incontinence of urine, the results were very evident. M. D'Arsonval had tried it on a celebrated French *savant*, who had been obliged to give up his work, owing to incontinence of urine, and curious shivering attacks, which came on without known reason. After the first injection all his troubles ceased like magic, and he was able to resume his studies. It is above all in anæmias, no matter what their cause, that Dr. Brown-Séquard finds the most use for his method, and he gives a remarkable case of a doctor whose method he does not approve of, but the demonstration of its wonderful efficiency he has seen. The doctor's wife, in question, was worn out after a metrorrhagia, that left her in a complete state of anæmia. He, believing in the virtue of testicular injections, had connection with his wife, and secured the sperm, which he injected under her skin a cubic centimeter at a time, with most wonderful results, and notwithstanding the fact that the metrorrhagia was repeated several times, the same treatment cured the patient every time.

This would seem to establish the fact that sperm has the same action as the testicular fluids of animals secured by trituration, but Dr. Brown-Séquard does not approve of this method, fearing septic complications from the injections. Most of the attempts made during last year were on persons really ill, but the real value of the method should be shown on old and weak persons, and Dr. Brown-Séquard, hopes that those who experiment with his method will publish their observations. In answer to the objection that was made against this system, that it acted by suggestion, Dr. Brown-Séquard does not deny the influences of suggestion, in all the affections of the nervous system, and he repeats that it is on the cerebro-spinal axis that the remedy acts, but he has made experiments to prove that it is not suggestion that acts. For instance, in certain cases several injections were needed before any effect was produced. In other cases colored water was used, telling the patient that a remarkable effect would be produced, but none was observed; but on the same patient being given an injection of the real matter, and being told it was nothing, a good effect was produced. Prof. Mairet, also injected the testicular fluids in idiots, who could not understand, and yet it was a success. The conclusion of the whole matter is the same as that announced by the eminent Professor, Brown Séquard, a year ago, that is, *that the testicular fluid has a powerful tonic influence on the system.*

ACCIDENTS FROM CHLOROFORM.

Dr. Laborde, who is the *chéf* of the physiological laboratory at the Paris Faculty of Medicine, has been making an interesting communication to the Academy of Medicine on the Preventive Treatment of Accidents that arise from Chloroformization. After having first shown that it is possible to prove by experiments on animals that there are two indications to act upon—one a primitive action, that is an irritant action, produced by the simple contact of the chloroform on the nasal mucous membrane (that is similar to that produced by the aspiration of ammonia), and that may produce nasal or laryngeal reflex action. The second phase is a reflex of arrest of the heart's action, that is produced by the intermediate action of the respiratory centers acting through the pneumogastric nerves on the heart. In the second place, the action of chloroform is toxic, and death is the consequence of an impregnation of all the tissues by the drug. This is explained by the works of Richet and Langlois, who have shown by experiments on animals that death has taken place because expiration in such cases is extremely difficult, and the products that should be carried off by expiration are not eliminated, but accumulate in the blood; and asphyxia is the result of the slightest obstacles to expiration, such as the tongue falling back, etc. There are also other cases of death under chloroform where the fatal accident comes on just at the moment when the surgeon is making his first cut. Here it is also a reflex, that results from the fact that sensibility is not yet abolished, and the nervous exitation produced by a section of the nerves in skin, causes a reflex action that produces an arrest of the heart's action. The clinical application of these facts is what most interests practical physicians, and M. Laborde gives this in his communication made to the academy yesterday. He says that the preventive treatment should obey two indications—1. To oppose the production of reflex action, of nasal or laryngeal origin; and 2. If such reflex action take place, to prevent their consequences by diminishing the irritability of the cardiac and respiratory centers of the medulla and decreasing the inhibiting power of the pneumogastric nerves on the heart.

For the first it has been proposed to use morphine, and it does diminish the peripheric sensibility, and prevents reflex syncope; but the clinicians fear that it predisposes to syncope, and M. Laborde has sough. for a drug that would not have any such actiont With M. Duquesnel he has obtained a special form of *narceine* that is perfectly soluble. (M. Laborde here showed a small bottle of liquid that contained a gramme of narceine in solution.) With this drug he has been able to procure a calm, tranquil sleep, without vomiting or consecutive torpor. In rabbits, one centigramme of this form of narceine has been enough, even when an inferior chloroform has been used. Another method used by M. Laborde is to brush the throat (pharynx and larynx) with a solution of cocaine, and thus prevent the dangerous reflex action produced by the irritating influence and the chloroform. As to diminishing the irritability of the pneumogastrics, two substances were used—one is curare, which, so far, cannot be used in man; but it is to be hoped that a curarine will be produced that can be used on human beings, before long. The second drug used was atropine, which acts well, but

needs to be given in doses that are not compatible with safety.

M. Laborde then spoke of the importance of dosing the chloroform by dropping a measured quantity, drop by drop, constantly, or by using Raphael Dubois' apparatus. A final precaution is to watch the respiration *every moment of the operation*, and the easiest way to do this is to use a pneumo-cardigraph machine, which waves a little flag, that gives the proper indication as the regular action of the respiration and the heart.

VACCINATION FROM GOATS.

The law making vaccination obligatory is becoming more and more urgent, and we must make provision for the day when it will be promulgated, when, in consequence, animal vaccine will everywhere take the place of vaccination from arm to arm. On this account no source from which vaccine can be derived should be neglected, above all, when it comes from an animal that is supposed to possess immunity from a number of the maladies that devastate humanity. This is the goat. M. Hervieux has lately read a paper before the Academy of Medicine showing that the goat can be inoculated with vaccine coming from the calf, or from human beings, and the effect of this inoculation is the same as that of the usual calf vaccine. Then, vaccination from the goat to a person's arm succeeds perfectly, on condition that the inoculation is made as soon as the vaccine is taken from the goat and the pustules have all the characters as the usual classical vaccine matter. The inoculation of goat vaccine that has been kept succeeds as well as the calf vaccine when it is done with the pulp, but not so well when done with the lymph. The vaccination of a person with goat's vaccine, that has already passed through the human body, gives results that represent the most fully-perfected type of the best vaccine matter. In one word, the animals of the goat species are just as apt to offer a good ground for the cultivation of vaccine matter as those of the bovine race, and the advantages are in favor of the goats.

THERAPEUTIC PROBLEMS.

Under this title Dr. Henri Huchard gives some interesting studies that are of great practical value. He supposes a case, of a regular variety, that is constantly seen in practice, and then gives the therapeutical indications and treatment for the case. We resume one of his last lessons of this kind.

Case I.—The patient has digestive troubles, with pyrosis, acid regurgitation, sometimes may vomit, and has gastric pain at night, which comes on two or three hours after eating and regularly. His appetite is good, sometimes very good; thirst constant. This state is often followed by loss of flesh, and may have for consequences stomach ulcer and dilatation of the stomach. If the gastric juice be analyzed, by the present method of sounding the stomach two hours after a trial meal, and the reactives of hydrochloric acid be used, it will be found that there is a hypersecretion of this acid; but, in the absence of this test, practical physicians can readily make the diagnosis by noting that the pain comes on at regular periods, at night, and two or three hours after dinner, and that food often stops it, and meat digestion will be found to proceed rapidly, while the starch foods take a long time to digest.

Diagnosis.—Hyperhydrochloric pseudo-gastralgia.

Therapeutic Indications.—There is here a false periodicity of pain, and quinine does more harm than good. The pain is not purely gastralgic, and therefore opium, etc., should not be given.

As the pain is due to the hyperacidity, give alkaline drugs in large doses to neutralize the acid, and institute the treatment as follows.

Hygienic Treatment.—Prevent all nervous causes, such as emotion, hard brain work, and any work just after meals. Suppress all alcohol, tea, coffee and spices, pickles and acids, salt meats, cheese, and game, as they call up a hypersecretion of gastric fluids. Also all pastry and fatty foods, and the starch foods, as they simply encumber the stomach and cause dilatation; fresh bread is, for the same reason, forbidden. Give milk in small doses, to which add Vichy water. Hashed meat and eggs are useful, as the albumen neutralizes the excess of HCl. They should chew well and for a long time all food, and take a light meal at night, and a small one during the night. They might have five meals, as follows: Morning, glass of milk; 11 A.M., breakfast of hashed meat and eggs and stale or toasted bread; 3. P.M., glass of milk; 7 P.M., light dinner, and during night one or more glasses of milk.

Local Treatment.—Neutralize the acidity by large doses of bicarbonate of soda (ten to twenty grammes a day), or magnesia that is decarbonized acts very well. The alkaline should be given away from meals, when the pain is most intense. Large doses must be insisted upon, as small ones only increase the acidity. As bicarb. soda is soluble, it is sometimes good to combine prepared chalk with the soda to form a protecting coat on the mucous membrane of the stomach. Equal parts may be prescribed. Intestinal atony should be combated by the usual means, and stomach washing out may be performed with alkaline liquids from time to time.

RESEMBLANCE BETWEEN FATIGUE AND HYSTERIA.

M. Féré calls attention to the fact that there is considerable resemblance between ordinary muscular fatigue and hysteria, and it is curious, when one thinks of it, how often contractions are experienced when one is fatigued, and irritability and a host of other symptoms that are seen in hysteria; and this has a practical bearing in that it gives an important therapeutical indication for treatment of hysterical states by complete rest.

TREATMENT OF ANASARCA BY THEOBROMINE.

This substance has caused considerable talk lately in Paris, owing to the trenchant Prof. G. Sée having stated that, "Notwithstanding the assertion of a German druggist, that salicylate of theobromine is more soluble than theobromine, I declare that it is insoluble." This called forth a letter from Dr. Gram, of Copenhagen, to the effect that he had said it was soluble, and that it was so while it contained fifty per cent. of theobromine, and it was very useful. It may be given in wafers, as follows:

℞.—Salicylate of sodii et theobromine, 3 grammes.
Divide in cachets No. 5.
S.—Give one wafer every three hours, and follow it by a drink of water or warm milk.

or, it may be given in solution, as follows:

℞.—Salicylate sodii et theobromine . 3 grammes.
Syr. bitter orange peel . . . . 30 "
Aquæ distill. . . . . 50 "
M. S.—Give a tablespoonful just before each meal.

THOMAS LINN, M.D.

Book Reviews.

NEURALGIA. By E. P. HURD, M.D. 1890. Geo. S. Davis, Detroit, Mich. Cloth, 50c.; paper, 25c. Pp. 153.

Neuralgia is a subject of great practical interest; as one may carry on a pretty large practice for many years without seeing a case of locomotor ataxy, but he can't practise a week without seeing neuralgia. When Anstie's book appeared, it gave so complete a summary of the subject, that anything following it must almost necessarily be built upon that as a foundation. Dr. Hurd has done this, and has paid special attention to the modern French clinicians Germain Sée, Dujardin-Beaumetz, Jaccoud, etc. While there is much material of value in the book, it should have been twice as large to do the subject justice. For instance, Anstie's admirable explanation of the points of Valleix, and their appearance late in the course of an inveterate neuralgia, is one of the things which one never forgets; while the simple statement that some good observers have failed to find these points leaves only an impression of uncertainty upon the mind. Brevity should never be carried so far as to sacrifice the sense.

MINERAL SPRINGS AND HEALTH RESORTS OF CALIFORNIA; with a complete chemical analysis of every important mineral water in the world. Illustrated. A Prize Essay. Annual Prize of the Medical Society of the State of California, Awarded April 20, 1889. By WINSLOW ANDERSON, M.D. San Francisco. The Bancroft Company, Publishers, 1890. Price, $1.50.

After a very good therapeutic index, the book opens with an introductory chapter on mineral springs, their varieties, uses, etc., and baths. He then takes up the California springs, in alphabetical order, giving analyses and other information concerning them. This occupies two hundred and three pages. It is not by any means complete, the majority of the springs named being merely mentioned. Many analyses are given, however, enough to justify the author's assertion that in California nearly every medicinal spring of note may be paralleled. The next seventy-two pages are occupied with analyses of the more important mineral waters of other States and of Europe. Then follow short chapters on the history of California, its climate, and a comparison with corresponding latitudes in the Old World. The book is valuable, and very interesting reading; the style is easy and discursive. This is the first specimen of the publisher's work we have seen; and the paper, typography, and binding are excellent. The illustrations are especially good; while the proof-reading could be improved.

Pamphlets.

Aus der gynækologischen Abtheilung des St. Francis Hospitals in New York. Die Laparatomien des Jahres 1889. Von Dr. George M. Edebohls, New York.

McGill University Annual Calendar. Faculty of Medicine. Fifty-eighth Session, 1890–'91. Montreal, 1890.

The Medical and Dental Register Directory and Intelligencer. Pennsylvania and Delaware. Wm. B. Atkinson, A.M., M.D., Editor. Philadelphia, George Keil, 1214–20 Filbert street, 1890.

Fifth Annual Report of the State Board of Health of the State of Maine. Augusta, 1890.

To fumigate a room slowly pour vinegar on a hot iron shovel. The doors and windows should be open.

The Medical Digest.

FISSURED NIPPLES can be protected from irritation during the nursing period by painting over the fissure a solution of rubber and chloroform.

CAUSES OF INSOMNIA.—These are arranged as follows by Folsom (*Boston Med. and Surg. Jour.*):

1. Perverse habit of sleeplessness.
2. External causes acting through the senses.
3. Excessive cerebration.
4. Reflex, especially indigestion; then genito-urinary.
5. Traumatisms; physical, psychic, or both.
6. Auto-toxemia; from syphilis, constipation, gout, etc., and habitual excess in coffee or drugs.
7. Exhaustion from disease, innutrition, or excess.
8. Vascular derangements; hepatic, cardiac, renal.
9. Vaso-motor.
10. Neurasthenia; causing hallucinations or astigmatism.
11. Neuropathic temperament.
12. Forerunner of mental disease; hysteria, hypochondria, and organic cerebral or spinal affections.
13. A form of insanity; an interchangeable psycho-neurosis.

AMATEUR DOCTORING.—Tuesday's *Globe* reports a case of a boy who had a fall and injured his knee. The sagacious parents of the lad, instead of seeking treatment from a reliable source, resorted to a *friend* who had a "reputation for medical skill." Alas, for bubble reputation. The boy died. Moral: The mere inunction of oil is not an absolute cure for compound fracture of the tibia. The *Globe*, in alluding to the case, remarks upon the folly of persons who put their trust in the medical advice supplied gratis through the columns of a newspaper, and concludes that even supposing the medical oracle be qualified to treat persons in his surgery, the class of persons who apply for information in this manner have not an exact, if graphic, method of description, the result being misleading, and the treatment often exactly wrong. But, of course, no one but the merest empiric would indulge in any such a system, and those who are stupid enough to seek the proffered advice deserve any fate that may befall them.—*Hospital Gazette.*

HINTS TO THE UNFORTUNATE.—A few suggestions, culled from accounts in the daily press, of cases of "accidental death" during the past week, may prove of service to those who are not ingenious enough to think of them for themselves: (1) Mix some coarse flour and strychnine to kill the rats with, then place the mixture in a jar, similar and as near as possible to that containing the family oatmeal. Prepare to shed this mortal coil! (2) Place some laudanum in an empty medicine bottle, and stand it alongside a bottle of physic on a table by your bedside; take a dose from the nearest bottle, in the dark; ten chances to one it's the laudanum. (3) Pour some carbolic acid into a beer-bottle, cork it, and put it aside in a cool spot; the next person who comes along with "a mouth on him," will find it a vast improvement on common or ginger beer. (4) Smear a piece of bread with phosphorus paste (rough on rats) and leave it in a cupboard well within reach of marauding youngsters; if their lives are insured, you will have no reason to regret the experiment.

—*Hospital Gazette.*

Medical News and Miscellany.

THE Roosevelt Hospital, New York, is being repainted.

SEVEN mad dogs were killed in New York last Saturday.

DR. THOMAS BIDDLE expects to spend the summer at Atlantic City.

AN epidemic resembling yellow fever is raging at Belize, Honduras.

DR. SALSER, of Philadelphia, has been staying at the Dennis, Atlantic City.

THE American Andrological and Syphilographical Association is the very newest.

DRS. ELDREDGE PRICE AND B. B. WILSON are frequent visitors at Longport, N. J.

KUESTNER says that the best female catheter is a simple glass tube, open at the ends.

DR. GEORGE F. KRETZ is the handsomest member of the Onanondo Club, in New York.

OXFORD University has decided to admit women to the examinations for the degree of M. B.

THE University of Louvain has added to the medical curriculum a course on medical ethics.

EVIDENCE accumulates as to the conveyance of diphtheria through the water used for drinking.

DR. A. P. BEALER has returned from the sea-side, and will return later for the balance of the season.

DR. D. O. LEWIS, of the Naval Hospital, Washington, has registered at the Star Villa, Cape May.

DR. W. H. BIRNEY, of West Philadelphia, is spending a few weeks at the Cape House, Cape May.

THE *Occidental Medical Times* reports the death of a child over three years old, from the bite of a tarantula.

DR. AND MRS. W. W. WEAVER, of Fortieth street and Woodland avenue, are visiting friends in Hanover.

DR. C. A. FRAME has been mentioned as a compromise candidate for the legislative nomination at Manayunk.

DR. JUDGE, of Philadelphia, went on a fishing excursion to Anglesea lately, and returned with several hundred fish.

DR. JOHN C. HALL, of the Germantown Insane Asylum, is taking a well-earned rest at the Irvington, Atlantic City.

THOUGH "Greenland's icy mountains" have been known a long time, they have never been boomed as a summer resort.

MEDINA reports some very obstinate cases of ulcerative keratitis which yielded to collyria of antipyrin in distilled water.

THE increase of insanity in Berlin has compelled the erection of a new asylum, to accommodate one thousand patients.

DR. JOHN B. SHOBER has been appointed one of the chiefs of the Surgical Department of the University Hospital Dispensary.

FOR metrorrhagia, Lawrence recommends plugging the cervix uteri with iodoform cotton, as simple and devoid of danger and pain.

A FEW cases of cholera continue to be reported in Valencia. There were three new cases and three deaths in Gandia, last week.

DR. EMILY HUNT, of the Philadelphia Hospital, has gone to Lansdowne for her vacation, to the home of her father, Dr. J. G. Hunt.

DR. ROSA KERSCHBAUMER is the first woman licensed to practice medicine in Austria. She is said to be an uncommonly able oculist.

DR. I. N. BROMELL and Mrs. Bromell, of North Fortieth street, will spend a portion of their vacation in Lancaster County and Atlantic City.

THE New York Academy of Medicine, 12 West Thirty first street, New York City, has removed to 17, 19 and 21 West Forty-third street, New York.

DR. BLOOMER, of the State Fencibles, has resigned his position as assistant-surgeon. Dr. Fitzpatrick, an up-town physician, is mentioned as his successor.

WE are still short of issues for August 10 and 17, 1889, and February 1 and March 1, 1890; to any one sending one of the above we still offer a dermatograph.

DR. CHARLES MEIGS WILSON spent the 4th of July at Atlantic City, and also stayed over Sunday; he returned to Philadelphia Monday morning, on the 7.10 train.

DR. FORMAD, the Coroner's physician, sailed from New York for Europe, with his wife, on the steamer Nevada, last week. He will be on the Continent for three months.

A RABID dog in England bit four persons. Three were treated by Pasteur and remain well; the fourth was treated by a constable who had a "remedy," and died of rabies.

H. F. BRADBURY, "Dean of Trinity University in Vermont," has been indicted by the Grand Jury of the United States District Court, Boston, for issuing bogus diplomas.

UNLOOKED-FOR success encourages expectation, and we are strongly of the opinion that too much is expected of electricity in the treatment of diseases of women.—*Lancet.*

CHOLERA is reported from Narbonne. *Le Petit Journal* states that several cases, one of which has resulted fatally, have occurred in the city of Narbonne, Department of Aude.

DR. HENRY M. WETHERILL, Secretary of the State Board of Lunacy, has returned from making a portion of his annual inspection of the insane asylums and hospitals throughout the State.

IN Egypt foundlings are placed in the charge of wet-nurses, who are inspected weekly and fined if either child or nurse is not well and in good condition. The plan is said to work well.

THE *Pacific Medical Journal* reports a case in which a man received a knife-wound penetrating the heart, continued the fight some time, and ran about one hundred yards before he fell, and died.

AN elderly married couple, who had long lived childless, journeyed to Germany, where, to their great surprise, the wife became a mother.

This item will doubtless have the effect of diverting the stream of travel from Germany to other lands less famed for germs.

DR. MARTIN, New York Board of Health chemist, decides that the sickness among those who ate Brinkman's ice cream was caused by the fermentation of old cream that had been left in the freezer.

TO REMOVE WARTS.—According to the American *Therapeutic Gazette*, castor oil, constantly applied for two to four or six weeks—that is once a day—has not failed in any case of any size or long standing.

A SENSATION has been created in Vienne by the discovery that the waters of the river Leitha, from Pottendorf to Landegg, are poisonous. Bathers have contracted pustular eruptions covering the entire body.

THE authorities of San Mateo County, California, are trying to make Dr. Whitwell put an eight-foot wall around his inebriate hospital and keep a guard at the gates. Their right to do so is to be tested in the courts.

DR. PORTER, of Fort Wayne, trephined a lad for epilepsy July 2. Considerable fluid was evacuated, and at last accounts the patient was doing well. The case was a severe one, from twenty-five to fifty spasms occurring daily.

SEVEN years' apprenticeship is required in England for the evolution of a journeyman plumber; and how any one can spend so long a time and learn so little is an inscrutable mystery to every one who subsequently employs him.

THE English scientific world is very much exercised over an invention purporting to be a remarkable instrument solving the problem of visual telegraphy. It is the joint invention of Prof. Hughes, F.R.S., and W. H. Preece, F.R.S., and is a fraud.

JACQUES, the French soldier, who is emulating Succi, the Italian faster, at the Aquarium, has completed the first two weeks of his proposed forty-two days' abstinence from food. He has lost sixteen pounds and five ounces. He is well, and confident of success.

THE outbreak of cholera in Spain has aroused the *British Medical Journal* to call for an improvement of London's water supply. The journal states that the last cholera epidemic cost London six thousand lives, and was traced to the pollution of the river Lee by one family.

JAMES MELVIN, a war veteran, portions of whose body had become ossified within a few years, and for whom a pension of $100 a month specially passed Congress last month, died, on Saturday, in Concord, Massachusetts. His suffering for several years past were excruciating.

DR. GREGORY HOVNANIAN, of Philadelphia, a native of Armenia, is at the Howell House, Asbury Park, where he will remain until August, when he will take the position of resident physician in the Blockley Hospital, at Philadelphia. He is a graduate of the Medico-Chirurgical College.

A DANGEROUS MINERAL WATER.—William T. Jeffries and S. S. Jordan have filed a bill in equity in the United States Circuit Court against the Geneva Magnetic Water Company, of Washington, D. C., W. L. Cresson, of Norristown, and Julius Hugle and J. C. Ergood, of Washington, to recover moneys in an odd business transaction. They purchased rights for the sale of the magnetic water in certain counties, understanding that it contained no organic matter, and, as they claim, have since discovered that it is injurious.

DR. BRUSTAR has reported to the Board of Health that 148 vessels, containing 2,822 passengers, were passed by him during the month of June. It will require $126,684 to conduct the Board of Health in 1891, according to the estimate of the Finance Committee. The revenue from all sources is estimated at $43,850.

DR. HENRY H. LONGSTREET, one of the oldest and most prominent physicians in Burlington county, died, last Sunday, after a brief illness. He had been in failing health for more than a year past, but had been confined to his home only a few days prior to his death. He was born in Monmouth county, New Jersey, January 11, 1819.

THE daughter of a prominent physician was admitted to the Pasteur Institute in New York last Sunday. She was bitten on the hand some time ago by a pet dog. The Cincinnati man, who was under treatment by Dr. Gibier for the past three weeks, was discharged last Sunday in perfect health. All the patients now under treatment are doing well.

PHILADELPHIA'S MORTALITY.—A record of interments in this city during the past six months: The weekly reports of interments in this city, published in THE TIMES AND REGISTER from week to week, have been collated, and the following tables have been prepared to contrast the number of interments during the past six months with corresponding periods of 1888 and 1889:

Year.	1888.	1889.	1890.

W. E. CHENERY, son of Dr. E. Chenery, of Boston, took his medical degree at Harvard on the 25th ult., and at once left for Europe, where he will spend the summer in visiting hospitals, studying, and observation. He has a sister, Hattie M., an art teacher, who has been abroad for more than a year in pursuit of her studies, with whom he hopes to return later in the fall.

JOHN WARSTER, of 1624 Dickinson street, Philadelphia, was drowned last Sunday at Atlantic City. Four doctors tried in vain to restore him to consciousness after rescuing him from the water. In these cases far more could be done if people would not crowd around the rescued. Fully 1,000 people were seen around this man by one of the publishers of this journal, so that it was almost impossible for air to get to him.

THE Health Department of New York has appointed fifty physicians of the summer corps, and on Wednesday they began their work among the poor of the tenements. Of the inestimable value of their work, which will continue during July and August, the following figures from last year will convey some idea: 264,000 families were visited, 16,148 sick people were prescribed for, 12,000 tickets for free excursions were distributed, and 50,000 circulars, containing simple instructions for the care of children during the hot months, were given away. And this work was chiefly among those unable, through poverty, to secure medical treatment and medicine, which the Board of Health furnished free. Through the co operation of the King's Daughters this season, even more will be completed than was last year.

THE CITY'S HEALTH.—During the week ending July 5, the causes of death reported were as follows:

Cholera infantum	141
Phthisis	67
Marasmus	44
Heart disease	28
Inanition	26
Old age	26
Inflammation of brain	22
Convulsions	20

DURING twenty years 3,503 prostitutes were registered at Brussels. Of these, when asked their reason for living in this way, 1,523 attributed it to poverty, 1,118 to sexual appetite, 420 attributed their fall to bad company, 316 tired of hard work and little pay, 101 abandoned by lovers, 10 quarreled with parents, 7 left by husbands, 4 quarreled with guardians, 3 had family quarrels, 2 were compelled to prostitute themselves by their husbands, and 1 by her parents. Nearly all said they would be only too glad to work if work could be secured. One of the greatest difficulties was that the markets were flooded with the products of convents, which undersold the work of women who had to support themselves. The strict regulation of prostitution exercised a wholesome effect in deterring women from entering this life. Poverty in Belgium renders prostitution a hard necessity; the alternative being starvation.

To Contributors and Correspondents.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from June 15, 1890, to June 28, 1890.

By direction of the Secretary of War, leave of absence for two months, to take effect August 6, 1890, is granted First Lieutenant William N. Suter, Assistant-Surgeon. Par. 3, S. O. 149, A. G. O., June 26, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending June 28, 1890.

John E. Page; Berryville, Va.; Robert M. Kennedy, Pottsville, Pa.; James M. Whitfield, Richmond, Va.; Lewis H. Stone, Litchfield, Conn.—commissioned Assistant-Surgeons in the Navy.

ATLEE, LOUIS W., Assistant-Surgeon. Detached from the U. S. S "Marion," and granted three months' leave.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the three weeks ending June 21, 1890.

GASSAWAY, J. M., Surgeon. When relieved at Cairo, Ill., to proceed to New Orleans, La., and assume command of the service at that station, June 4, 1890.

STONER, G. W., Surgeon. Granted leave of absence for three days, June 18, 1890.

WASDIN, EUGENE, Passed Assistant Surgeon. Granted leave of absence for fourteen days, June 5 and 10, 1890.

WHITE, J. H., Passed Assistant-Surgeon. To proceed to Savannah, Ga., on special duty, June 9, 1890.

HEATH, F. C., Assistant-Surgeon. Granted leave of absence for fifty-eight days, June 10, 1890.

MAGRUDER, G. M., Assistant-Surgeon. Granted leave of absence for twenty days, June 2, 1890. Ordered to examination for promotion, June 5, 1890.

WOODWARD, R. M., Assistant-Surgeon. Relieved from duty at Chicago, Ill., to assume command of service at Cairo, Ill., June 4, 1890.

CONDICT, A. W., Assistant-Surgeon. Upon expiration of leave of absence, to report to Medical officer in command at Chicago, Ill., for duty, June 4, 1890.

RESIGNATION.

HEATH, F. C., Assistant-Surgeon. Resignation accepted by the President (to take effect Aug. 31, 1890), June 10, 1890.

Medical Index.

A weekly list of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Physiologische Bemerkungen über die Hypertrophie und Dilation des Herzens, Frey. Deutsches Archiv f. Klin. Med.
Perinterine and perityphlitic abscesses, Mayo. Northw. Lanc.
Prevention of puerperal fever, Britton. Canada Lancet.
Paralysis of the superior oblique, cured by tenotomy of the superior rectus of the same eye, Webster. Med. Rec.
Prophylaxie de la syphilis et de la prostitution, Mericourt. Bulletin de l'Academie de Med.
Posterior displacements of uterus, Boldt. Amer. Jour. Obst.
Prolapse of the female urethra, and true cystocele or vesico-vaginal hernia, Munde. *Ibid.*
Pleuritic effusions, Atkins. Amer. Pract. and News.
Pyosalpynx, intest. laceration, omental grafts, Carpenter. *Ib.*
Phthisis pulmonalis, Robison. The Med. Age.
Précis of operations performed in wards of the first surgeon Med. Coll. Hosp. during year 1890, McLeod. Ind. Med. Gaz.
Pleuresie interlobaire gauche suppurée, Letulle. La Med. Mod.
Points in the study of inebriety, Field. N. Y. Med. Jour.
Poisoning by oil of cedar, Ellison. Therap. Gaz.
Physician on the witness stand, Hammond. St. Louis Cour.
Pruritis following an electric shock, Grindon. *Ibid.*
Resection of cæcum for carcinoma, Senn. J. Am. Med. Ass'n.
Rapid dilation of the uterus, Carpenter. Cleveland Med. Gaz.
Removal of a fibrous polypus from the base of skull. Girdlestone. Austral. Med. Jour.
Railway sanitation, Conn. Jour. Nat. Ass'n Railw. Surg.
Ricerche sulla vitalita del virus tetanico nelle acque, Schwarz. La Rif. Med.
Retinal detachments injection of iodine into vitreous, Phillips. Atlanta Med. Surg. Jour.
Relation of formative matter to disease, Foote. Kansas Med. J.
Rougeole et rubeole, Talamon. La Med. Mod.
Risultati statistici delle vaccinazioni antirabiche nell' istituto di Palermo, Blasi e Travali. La Rif. Med.
Ricerche chimiche e tossicologiche sull' ecgonina, Mussi. *Ib.*
Report on the progress of surgery, Dixon. Med. Mirror.
Radical cure of hernia, Bishop. The Lancet.
Recent experience with electricity in gynecology, Munde. Amer. Jour. of Obstetrics.
Relative value of different suture materials, Steele. Med. Age.
Relation of pneumonia to influenza in Boston, Shattuck. N. Y. Med. Jour.
Sugli accessi convulsivi. La Rif. Med.
Sull' azione fisiologica della digitalina, Masi. *Ibid.*
Sulla furuncolosi dei visceri, Vivaldi. *Ibid.*
Sulla cura razionale ortopedica della lussazione iliaca comune congenita del femore, Paci. Arch. di Ortoped.
Strangulated inguinal hernia, Muva. Sei-i-Kwai Med. Jour.
Sulla vera interpretazione delle alterazioni della mucosa uterina nel carcinoma della porzione vaginale e nei miofibromi, Curatulo. La Rif. Med.
Sulla prognosi e cura della polmonite fibrinosa. *Ibid.*
Sulla influenza, osservazioni batterioscopiche, Sirena. *Ibid.*
Seconda e terza operazione cesarea conservatrice, angio-colite suppurativa. *Ibid.*
Sull' aumento dell' acido solforico accoppiato nelle urine in segnito alla somministrazione di fenacetina, azione tossica della fenacetina, Ubaldi. *Ibid.*
Sur la syncope respiratoire et les accidents de la chloroformisation, Laborde. Bulletin de l'Acad. de Med.
Sarcom al ovarului drept. laparotomie, extirparea neoplasmului, Kiriac. Clinica.
Studiu asupra anesthesiei cu dose minime de chloroform, de Florea Simeonescu. *Ibid.*
Sterilization of water, Currier. Med. Rec.
Stricture of the male urethra, Engram. South. Med. Rec.
Skin grafting, Cheyne. Practitioner.
Sur l'action physiologique des anesthesiques en general et du chloroforme en particulier, Laborde. La Trib. Med.
Splenectomy, report of case, Willien. Ind. Med. Jour.
Syphilodermata, Hardaway. St. Louis Courier of Med.
Surgical treatment of fixed membranous opacities in the vitreous humor, Bull. Ophthalmic Rev.
Sur l'etiologie de la paralysie infantile, Joffroy. Le Bull. Med.
Turpentine in croup, McCurdy. Columbus Med. Jour.
Technique of intestinal surgery, Robinson. Clevel Med. Gaz.
Toxic effect of acetanilid, Taylor. Cin. Lancet-Clinic.
Trachom tuberculos, Manolescu. Clinica.
Typhoid, typho-malarial, and continued fevers, Smith. Va. Med. Monthly.
Tubercular laryngitis, Bronner. Med. Press.
Troubles divers de la nutrition à la suite de dermatite artificielle, Juinquad. La Trib. Med.
Transient alimentary glycosuria and its practical bearings in the selection of risks for life insurance, Warren. N. Y. Med. Jour.
Therapeutic uses of buttermilk, Ward. Therap. Gaz.
Tumor of the cerebellum, Dalton. St. Louis Cour. of Med.
Ueber örtlich secretionshemmende und secretionbefördernde Wirkung, Schutz. Arch. f. Exp. Path. Pharm.
Urticaria pigmentosa, Doutrelepont. Arch. f. Derm. u. Syph.
Ueber den Favuspilz bei Favus herpebicus, Jadassohn. *Ibid.*
Ueber die Wirkung des positiven Pols des constanten Stroms auf die Mikroorganismen, besonders die Milzbrandbacillen, Apostoli und Laquerriere. Berl. Klin. Wochenschrift.
Un caso di avvelenamento per anici, Cervelli. Giorn. Med.
Un caso di polmonite contusiva, Minossi. La Rif. Med.
Ueber den Färbungswiderstand lebender Pilzzellen, Buchner. Centralblatt. für Bakt.
Ueber die in Dysenterie und dysenterischem Leberabscess vorhandenen Amœba, Osler. *Ibid.*
Ueber Milchsterilisation, Strub. *Ibid.*
Ueber die Kupferoxyd-reducirenden Substanzzen des Harns unter physiologischen und pathologischen Verhältnissen, mit specieller Berücksichtigung des Nachweises und der Bestimmung geringer Mengen von Traubenzucker, sowie der Frage seines Vorhandenseins im normalen Harn, Moritz. Deutsches Archiv f. Klin. Med.
Ueber den Pulsus differus und seine Bedeutung bei Erkrankungen des Aortenbogens, Ziemssen. *Ibid.*

THE RELATION OF BACTERIA TO PRACTICAL SURGERY.[1]

BY JOHN B. ROBERTS, M.D.

THE revolution which has occurred in practical surgery since the discovery of the relation of micro-organisms to the complications occurring in wounds, has caused me to take up this subject for discussion. Although many of my hearers may be familiar with the germ theory of disease, it is possible that it may interest some to have put before them in a short address a few points in bacteriology, which are of value to the practical surgeon.

It must be remembered that the groups of symptoms which were formerly classed under the heads of "inflammatory fever," "symptomatic fever," "traumatic fever," "hectic fever," and similar terms, varying in name with the surgeon using them, or with the location of the disease, are now known to be due to the invasion of the wound by microscopic plants. These bacteria, after entering the blood current at the wound, multiply with such prodigious rapidity that the whole system gives evidence of their existence. Suppuration of wounds is undoubtedly due to these organisms, as is tubercular disease, whether of surgical or medical character. Tetanus, erysipelas, and many other surgical conditions have been almost proved to be the result of infection by similar microscopic plants, which, though acting in the same way, have varying forms and life histories.

A distinction must be made between the "yeast-plants," one of which produces thrush, and the "mould-plants," the existence of some of which, as parasites in the skin, give rise to certain cutaneous diseases. These two classes of vegetable parasites are foreign to the present topic, which is surgery, and I shall, therefore, confine my remarks to that group of vegetable parasites to which the term bacteria has been given. These are the micro organisms whose activities and method of growth particularly concerns the surgeon.

The individual plants are so minute that it takes in the neighborhood of ten or fifteen hundred of them grouped together to cover a spot as large as the full stop, or period, used in punctuating an ordinary newspaper. The rough estimate applies to the globular and egg-shaped bacteria, to which is given the name "coccus" (pleural, cocci). The cane or rod-shaped bacteria are rather larger plants. Fifteen hundred of them placed end to end would stretch across the head of a pin. Because of the resemblance of these latter to a walking-stick, they have been termed "bacillus" (pleural, bacilli). The bacteria most interesting to the surgeon belong to the cocci and bacilli. There are other forms which bacteriologists have dubbed with similar descriptive names, but they are more interesting to the physician than the surgeon. Many micro-organisms, whether cocci, bacilli, or of other shapes, are harmless; hence they are called non-pathogenic, to distinguish them from the disease-producing or pathogenic germs.

As many trees have the same shape and a similar method of growing, but bear different fruits, in one edible and in another poisonous, so two bacteria may look alike, to the microscopist's eye, and grow much in the same way; but one will cause no disease, while the other will produce tuberculosis of the lungs or brain.

Many scores of bacteria have been, by patient

[1] Read at the meeting of the Medical Society of the State of Pennsylvania, held at Pittsburg, Pa., June 11, 1890.

study, differentiated from their fellows and given distinctive names. Their nomenclature corresponds in classification and arrangement with the nomenclature adopted in other departments of botany. Thus we have the pus causing chain-coccus (streptococcus pyogenes), so called because it is globular in shape, because it grows with the individual plants attached to each other, or arranged in a row like a chain of beads on a string, and because it produces pus. In a similar way we have the pus-causing grape coccus of a golden color (staphylococcus pyogenes aureus). It grows with the individual plants arranged somewhat after the manner of a bunch of grapes, and when millions of them are collected together the mass has a golden yellow hue. Again, we have the bacillus tuberculosis, the rod-shaped plant, which is known to cause tuberculosis of the lungs, joints, brain, etc.

It is hardly astonishing that these fruitful sources of disease have so long remained undetected when their microscopic size is borne in mind. That some of them do cause disease is indisputable, since bacterologists have, by their watchful and careful methods, separated a single plant from its surroundings and congeners, planted it free from all contamination, and observed it produce an infinitesimal brood of its own kind. Animals and patients inoculated with the plant thus cultivated have rapidly become subjects of the special disease which the particular plant was supposed to produce. The difficulty of such investigation becomes apparent when it is remembered that under the microscope many of these forms of vegetable life are identical in appearance, and that it is only by observing their growth, when cultivated in the proper soil, that they can be distinguished from each other. In certain cases it is quite difficult to distingush them by the physical appearances produced during their growth. Then, it is only after an animal has been inoculated with them that the individual parasite can be accurately recognized and called by name. It is known, then, by the results it is capable of producing.

The various forms of bacteria are recognized, as I have said, by their method of growth, and by their shape. Another means of recognition is their individual peculiarity of taking certain dyes, so that special plants can be recognized under the microscope by the color given to them, which they refuse to give up when treated with chemical substances which remove these stains from, or bleach all the other tissues which, at first, were similarly stained.

The similarity between bacteria and the ordinary plants, with which florists are familiar, is indeed remarkable. Bacteria grow in animal and other albuminous fluids, and it is just as essential for them to have a suitable soil as it is for the corn or wheat that the farmer plants in his field. By altering the character of the albuminous fluid in which the microorganism finds sustenance, these small plants can be given a vigorous growth, or may be actually starved to death. The farmer knows that it is impossible for him to grow the same crop year after year in the same field, and he is, therefore, compelled to rotate his crops. So is it with these microscopic plants which we are considering. After a time, the culture fluid or soil becomes so exhausted of its needed constituents by the immense number of plants that have grown in it that it is unfit for their life and development. Then this particular form will no longer thrive, but some other form of bacterium may find in it the properties required for functional activity, and grow vigorously. It is probably that this exhaustion or absence of proper soil is an important agent in protecting man against continuous sickness, due to infection with bacteria. The ever-present bacteria often gains access to man's blood through external wounds, or the lungs and digestive tract; but unless a soil suited for their development is found in his fluids the plants will not grow. If they do not grow, and increase in numbers, they can do little harm.

Again, there are certain bacteria which are so antagonistic to each other that it is impossible to make them grow in company, or to co-exist in the blood of the same individual. For example, an animal inoculated with erysipelas germs cannot be successfully inoculated immediately afterward with the germs of malignant pustule. On the other hand, however, there are some micro-organisms which flourish luxuriantly when planted together in the same fluid, somewhat after the manner of pumpkins and Indian corn growing between the same fence rails. Others seem unwilling to grow alone, and only flourish when planted along with another germ. The antagonism between two bacteria is illustrated by the impossibility of having a good crop of grain in a field over-run with daisies. It is very evident, therefore that bacteriology is a branch of botany, and that nature shows the same tendencies in these minute plants as it does in the large vegetable world visible to our unaided eyes.

As the horticulturalist is able to alter the character of his plants by changing the circumstances under which they live, so can the bacteriologist change the vital processes and activities of bacteria by chemical and other manipulations of the culture substances in which these organisms grow. The power of bacteria to cause pathological changes may thus be weakened or attenuated; in other words, their functional power for evil is taken from them by alterations in the soil, the pathogenic or disease-producing power may be increased by similar, though not identical, alterations. The rapidity of their multiplication may be accelerated, or they may be compelled to lie dormant and inactive for a time; and, on the other hand, by exhausting the constituents of the soil upon which they depend for life, they may be killed.

The destruction of bacteria by means of heat and antiseptics is the essence of modern surgery. It is then by preventing access of these parasitic plants to the human organism (aseptic surgery), or the destruction of them by chemical agents and heat (antiseptic surgery), that we are now enabled to invade regions of the body by operative attacks which a few years ago were sacred.

It is a most curious fact, also, that it is possible, by selecting and cultivating only the lighter colored specimens of a certain purple bacterium, for the bacteriologist, to finally obtain a plant which is nearly white, but which has the essential characteristics of the original purple fungus. In this we see the same power which the florist has to alter the color of the petals of his flowers by various methods of selective breeding.

When the disease-producing bacteria gain access to the tissues and blood of human and other animals by means of wounds, or through an inflamed respiratory or alimentary mucous membrane, they produce pathological effects, provided there is not sufficient resistance and health-power in the animal's tissues to successfully antagonize the deleterious influence of the invading parasitic fungus. It is the rapid multiplication of this germ which furnishes a *continuous* irritation that enables them to have such a disastrous effect upon the tissue and the animal. If the tissues

had only the original dose of microbes to deal with the warfare between health and disease would be less uncertain in outcome. Victory would actually be on the side of the tissues and health.

The immediate cause of the pathogenic influence is probably the chemical excretions which are given out by these microscopic organisms. All plants and animals require a certain number of substances to be taken into their organisms for preservation of their vital activities. After these substances have been utilized there occurs an excretion of other chemical products. It is probably the excretions of the many millions of micro-organisms circulating in the blood that give rise to the disease characteristic of the fungus with which the animal has been infected. The condition called sapræmia, or septic intoxication, for example, is undoubtedly due to the entrance of the excretory products of putrefaction-bacteri into the circulation. This can be proved by injecting into an animal a small portion of these products obtained from cultures of the germs of putrefaction. Characteristic symptoms will at once be exhibited.

Septicæmia is a similar condition, due to the presence of putrefactive organisms themselves, and hence their products or ptomaines also in the blood. The rapidity of their multiplication in this albuminous soil, and the great amount of excretion from these numerous fungi, make the condition more serious than sapræmia. Clinically, the two conditions occur together.

The rapidity with which symptoms may arise after inoculation of small wounds with a very few germs, will be apparent when it is stated that one parasitic plant of this kind, may, by its rapidity of multiplication, give rise to fifteen or sixteen million individuals within the twenty-four hours. The enormous increase which takes place within three or four days is almost incalculable. It has been estimated that a bacillus only about one-thousandth of an inch in length, would, under favorable conditions, develop a brood of progeny, in less than four days, which would make a mass of fungi sufficient to fill all the oceans of the world, if they all had a depth of one mile.

Bacteria are present everywhere. They exist in the water, earth, air, and within our respiratory and digestive tract. Our skin is covered with millions of them ; as is every article about us. They can circulate in the blood and lymph, and reach every tissue and part of our organism by passing through the walls of the capillaries. Fortunately, they require certain conditions of temperature, moisture, air, and organic food for existence and preservation of their vital activities.

If their surroundings are too hot, too cold, or too dry, or if they do not supply a proper quantity and quality of food, the bacterium becomes inactive, until the surrounding circumstances change, or may die absolutely. The spores, which finally become full fledged bacteria, are able to stand a more unfavorable environment than the adult bacteria. Many spores and adults, however, perish.

Each kind of bacterium requires its own special environment to permit it to grow and flourish. The frequency with which an unfavorable combination of circumstances occurs, limits greatly the disease-producing power of the pathogenic bacteria.

Many bacteria, moreover, are harmless, and do not produce disease even when present in the blood and tissues. Besides this, the whole blood cells are perpetually waging war against the bacteria in our bodies. They take the bacteria into their interiors and render them harmless by eating them up, so to speak ; or they crowd together and form a wall of white blood cells around the place were the bacteria have entered the tissues, thus forming a barrier to cut off the food supply to the germ, and, perhaps, to prevent them entering the general blood current.

The war between the white blood cells and the bacteria is a bitter one. Many bacteria are killed ; but on the other hand, the life of many blood cells is sacrificed, by the bacteria poisoning them with ptomanies. The tissue cells, if healthy, offer great resistance to the attack of the army of bacteria. Hence, if the white cells are vigorous and abundant at the site of the battle, defeat may come to the bacteria, and the patient suffer nothing from the attempt of these vegetable parasites to harm him. If, on the other hand, the tissues have a low resistant power, because of general debility of the patient, or a local debility of the tissues themselves, and the white cells be weakly and not abundant, the bacteria will gain the victory, get access to the general blood current, and invade every portion of the organism. Thus a general or a local disease will be caused, varying with the species of bacteria with which the patient has been infected, and the degree of resistance on the part of the tissues still existing.

From what has been stated it must be evident that the bacterial origins of disease depend upon the presence of a disease producing fungus ; a diminution of the normal healthy tissue resistance to bacterial invasion. If there is no fungus present, the disease caused by such fungus cannot develop. If the fungus be present, and the normal healthy tissue resistance be undiminished, it is probable that disease will not occur. As soon, however, as overwork, injury of a mechanical kind, or any other cause, diminishes the local or general resistance of the tissues individual, the bacteria have the upper hand, and are liable to produce their malign effect.

Many conditions favor the bacterial attack. The patient's tissues may have an inherited peculiarity, which renders it easy for the bacteria to find a good soil for development ; an old injury or inflammation may render the tissues less resistant than usual ; the point at which inoculation has occurred may have certain anatomical peculiarities which make it a good place in which bacteria may multiply ; the blood may have undergone certain chemical changes which render it a better soil than usual for the rapid growth of these parasitic plants.

The number of bacteria originally present makes a difference also. It is readily understood that the tissues and white blood cells would find it more difficult to repel the invasion of an army of a million microbes than the attack of a squad of ten similar fungi. I have said that the experimenter can weaken and augment the virulence of bacteria by manipulating their surroundings in the laboratory. It is probable that such a change occurs in nature. If so, some bacteria are more virulent than others of the same species ; some less virulent. A few of the less virulent disposition would be more readily killed by the white cells and tissues than would a large number of the more violent ones. At other times the danger from microbic infection is greater, because there are two species introduced at the same time ; and these two multiply more vigorously when together than when separated. There are, in fact, two allied hosts trying to destroy the blood cells and tissues. This occurs when the bacteria of putrefaction and the bacteria of suppuration are introduced into the tissues at the same time. The former causes sapræmia and septicæmia, the latter causes suppuration. The bac-

teria of tuberculosis are said to act more viciously if accompanied by the bacteria of putrefaction. Osteomyelitis is of greater severity, it is believed, if due to a mixed infection with both the white and golden grapecoccus of suppuration.

I have previously mentioned that the bacteria of malignant pustule are powerless to do harm when the germs of erysipelas are present in the tissues and blood. This is an example of the way in which one species of bacteria may actually aid the white cells, lencocylis and tissues in repelling an invasion of disease-producing microbes.

Having now occupied a portion of the time allotted to me, in giving a crude and hurried account of the characteristics of bacteria, let me conclude my address by discussing the relation of bacteria to the diseases most frequently met with by the surgeon. Mechanical irritations produce very temporary and slight irritation and inflammation, which rapidly subside because of the tendency of nature to restore the parts to health. Severe injuries even will therefore soon be followed by healing and cure, if no germs enter the wound.

Suppuration of operative and accidental wounds was, until recently, supposed to be essential. We now know, however, that wounds will not suppurate if kept perfectly free from one of the dozen or more forms of bacteria that are known to give rise to the formation of pus.

The doctrine of present surgical pathology is, that suppuration will not take place if pus-forming bacteria are kept out of the wound, which will then heal by first intention without inflammation, and without inflammatory fever.

In making this statement I am not unaware that there is a certain amount of fever following various severe wounds within twenty-four hours, even when no suppuration occurs. This wound-fever, however, is transitory, not high, and entirely different from the prolonged condition of high temperature formerly observed, nearly always, after operations and injuries. The occurrence of this inflammatory, traumatic, surgical, or symptomatic fever, as it was formerly called, means that the patient has been subjected to the poisonous influence of putrefactive germs.

We now know why it is that certain cases of suppuration are not circumscribed but diffuse, so that the pus dissects up the fascias and muscles, and destroys with great rapidity the cellular tissues. This form of suppuration is due to a particular form of bacteria called the pus-forming "chain-coccus." Circumscribed abscesses, however, are due to one or more of the other pus-causing micro-organisms. How much more intelligent is this explanation than the old one that diffuse abscesses depended upon some curious characteristics of the patient. It is a satisfaction to know that the two forms of abscess differ because they are the result of inoculation with different germs. It is practically a fact that wherever there is found a diffuse abscess, there will be discovered the streptococcus pyogenes, which is the name of the chain-coccus above mentioned.

So also is it now easy to understand the formation of what the old surgeons called cold abscesses, and to account for the difference in appearance of its puriform secretion from the pus of acute abscess. Careful search in the fluid coming from such cold abscesses reveals the presence of the bacillus of tuberculosis, and proves that the "cold abscess" is not a true abscess, but a lesion of local tuberculosis. Easy it is now to understand the similarity between the "cold abscess" of the cervical region and the "cold abscess" of the lung in a phthisical patient. Both of them are, in fact, simply the result of invasion of the tissues with the ubiquitous tubercle bacillus; and are not due to pus-forming bacteria.

Formerly it was common to speak of the scrofulous diathesis, and attempts were made to describe the characteristic appearance of skin and hair pertaining to persons supposed to be of scrofulous tendency. The attempt was unsuccessful and unsatisfactory. The reason is now clear, because it is known that brunette and blonde, old and young, can become infected with the tubercle bacillus. Since the condition depends upon whether the tissues of one or other become infected with the ever-present bacillus of tubercle, it is evident that there can be no distinctive diathesis. In truth, it is more than probable that the cutaneous disease so long described as lupus vulgaris, is simply a tubercular ulcer of the skin, and not a special disease of unknown causation.

The metastatic abscesses of pyæmia are clearly explained when the surgeon remembers that they are simply due to a softened blood-clot, containing pus-forming germs, being carried through the circulation and lodged in some of the small capillaries.

A patient suffering with numerous boils upon his skin, has often been a puzzle to his physician, who has in vain attempted to find some cause for the trouble in his general health alone. Had he known that every boil owed its origin to pus-bacteria, which had infected a sweat-gland, or hair follicle, the treatment would probably have been more efficacious. The suppurative pus-germs either lodged upon the surface of the skin from the exterior, or deposited from the current of blood in which they have been carried to the spot.

I have not taken time to go into a discussion of the methods by which the relationship of micro-organisms to surgical affections has been established; but the absolute necessity for every surgeon to be fully alive to the inestimable value of aseptic and antiseptic surgery, has led me to make the foregoing statements as a sort of resumé of the relation of the germ theory of disease to surgical practice. It is clearly the duty of every man who attempts to practice surgery to prevent, by every means in his power, the access of germs, whether of suppuration, putrefaction, erysipelas, tubercle, tetanus, or any other disease, to the wounds of his patient. This, as we all know, can be done by absolute bacteriological cleanliness. It is best, however, not to rely solely upon absolute cleanliness, which is almost unattainable, but to secure further protection by the use of antiseptic solutions. I am fully of the opinion that chemical antiseptics would be needless, if absolute freedom from germs was easily obtained. When I know that even such an enthusiast as I, myself, am continually liable to neglect, or to forget some step in this direction, I feel that the additional security of chemical antiseptics is of great value. It is difficult to convince the majority of physicians, and even ourselves, that to touch a finger to a door knob, to an assistant's clothing, or to one's own body, may vitiate the entire operation by introducing one or two microbic germs into the wound.

An illustration of how carefully the various steps of an operation should be guarded is afforded by the appended rules, which I have adopted at the Woman's Hospital, of Philadelphia, for the guidance of assistants and nurses. If such rules were taught every medical student, and every physician entering practice, as earnestly as the paragraphs of the catechism are taught the Sunday-school pupil, and they cer-

tainly ought to be so taught, the occurrence of suppuration, hectic fever, septicæmia, pyæmia and surgical erysipelas would be practically unknown. Death, then, would seldom occur after surgical operations, except from hemorrhage, shock, or exhaustion.

With this feeble plea, Mr. President and members of the Society, I hope to create a realization of the necessity for knowledge and interest in the direction of the practical bacteriology, for this is the foundation of modern surgery. There is, unfortunately, a great deal of abominable work done under the names of antiseptic and aseptic surgery, because the simplest facts of bacteriology are not familiar to the operator. I have taken the liberty of bringing here a number of culture tubes, containing beautiful specimens of some of the more common and interesting bacteria. The slimy masses seen on the surfaces of jelly contained in the tubes are many millions of individual plants, which have aggregated themselves in various forms as they have been developed as the progeny of the few parent cells planted in the jelly as a nutrient medium or soil.

A CONTRIBUTION TO THE ETIOLOGY OF DIPHTHERIA.[1]

By E. KLEIN, M.D., F.R.S.

THE microbe, which was first described by Klebs at the Weisbaden Congress in 1883, then isolated and grown in artificial cultures by Loeffler ("Mitth. aus dem K. Gesundheitsamte," vol. ii) from human diphtheritic membrane, was shown by this observer to act virulently on various animals. The Klebs-Loeffler bacillus—by which name the diphtheria microbe is known—is the one with which also Roux and Yersin ("Annales de l'Institut Pasteur," II, No. 12) obtained positive results on guinea-pigs.

In the reports of the Medical Officer of the Local Government Board for 1888–89 and 1889–90, I have shown that there occur in diphtheritic membranes two species of bacilli, very similar in morphological respects, and also in cultures on serum and on agar, but differing from one another in this, that one species (Klebs-Loeffler bacillus No. 1) is not constant in diphtheritic membranes, does not grow on solid gelatine at 19–20° C., and does not act pathogenically on animals; the other species (Klebs-Loeffler bacillus No. 2) is constant in diphtheritic membranes; in fact, is present even in the deeper layers of the membranes in great masses and almost in pure culture, acts very virulently on animals, and grows well on gelatine at 10–20° C. Loeffler, and after him other observers (Flugge, "Die Mikro-organismen," 1886) considered it as a character of the diphtheria bacillus that it does not grow on gelatine below 22° C.; but this character, though true of the Klebs-Loeffler species No. 1, does not appertain to the diphtheria bacillus species No. 2. In fact, there is no difficulty in obtaining pure cultures of this bacillus on gelatine if a particle of diphtheritic membrane be taken and well shaken in two or three successive lots of sterile salt solution, and from the last lot plate cultivations on gelatine are made. In this way I have obtained the diphtheria bacillus in great numbers of colonies and in pure culture. Zarniko ("Centr. f. Bact. u. Parasit.," vol. vi, page 154) and Escherich (*Ibid.*, vol. vii, p. 8) both state that the diphtheritic bacillus does grow on gelatine below 20° C.

This bacillus diphtheriæ acts very virulently on guinea-pigs on subcutaneous inoculation: at the seat of the injection a tumor is produced, which, in its pathology and in microscopic sections, completely resembles the diphtheritic tissue of the human. In human diphtheria, the diphtheria bacillus is present only in the diphtheritic membrane, but neither in the blood nor in the diseased viscera; the same holds good for the experimental guinea-pigs. In subcutaneous inoculation with artificial culture, though it causes in these animals acute disease and death—the lungs, intestine and kidney are greatly congested—the diphtheria bacillus remains limited to the seat of inoculation. It was for these reasons that Loeffler concluded that in diphtheria the diphtheritic membrane alone is the seat of the multiplication of the diphtheria bacillus, and that here a chemical poison is produced, which, absorbed into the system, causes the general diseased condition, and eventually death. Roux and Yersin have then separated from artificial broth cultures the bacilli and the chemical products, and, by the injection of these latter alone into guinea-pigs, have produced a general effect. I have, in this year's report to the Medical Officer of the Local Government Board (1889–90), shown that, in these experiments of injections of cultures into guinea-pigs, an active multiplication of the diphtheria bacilli at the seat of inoculation can be demonstrated by culture experiments; from the local diphtheritic tumor and the nearest lymph-glands the diphtheria bacilli can be obtained in pure culture on gelatine.

On various occasions during the last three years information has reached me by Health Officers (Dr. Downes, Mr. Shirley Murphy, Dr. Thursfield) as to a curious relation existing between a mysterious cat disease and human diphtheria in this manner: that a cat or cats were taken ill with a pulmonary disease, and, while ill, were nursed by children, and then these latter sickened with well-marked diphtheria. Or children were taken ill with diphtheria, and either at the same time or afterwards the cat or cats sickened. The disease in the cat was described as an acute lung trouble: the animals were quiet, did not feed, and seemed not to be able to swallow. In some cases they recovered; in others they became emaciated, while the lung trouble increased, and ultimately they died. In one instance—in the north of London, in the spring of 1889—this cat malady, occurring in a house where diphtheria soon afterwards appeared amongst the children, was of a widespread nature. A veterinary surgeon—Dr. Daniel—informed me that, at that time, he had several patients among cats affected with the disease, consisting in an acute catarrhal affection, chiefly of the respiratory passages. He furnished me with two such animals: one that, after an illness of several weeks, had died, another that was sent to me in a highly emaciated state, affected with broncho-pneumonia; this animal was paralyzed on the hind limbs. In both instances the post-mortem examination showed severe lung disease, broncho-pneumonia, and large white kidneys, due to fatty degeneration of the entire cortex. A similar condition is met with in the human subject in diphtheria. Further, I received from Dr. Thursfield, of Shrewsbury, the body of a cat that had died after a few days' illness from pneumonia, in a house in which children were ill with diphtheria; another cat in the same house, that became next ill with the same lung trouble, also succumbed. The post-mortem examination of the

[1] This research was undertaken for the Medical Department of the Local Government Board, and is communicated to the Royal Society with the permission of the Medical Officer. A paper read before the Royal Medical Society, London, May 22, 1890; reprinted from proof-sheets given by Dr. Klein to Dr. Hewitt. Advance sheets of "Public Health in Minnesota," Vol. VI., No. 4.

animal that I received showed severe broncho-pneumonia and large white kidneys, the entire cortex being in a state of fatty degeneration.

Subcutaneous inoculations of cats were carried out with particles of fresh human diphtheritic membranes and with cultures of the diphtheria bacillus (report of Medical Officer of the Local Government Board, 1889–90); thereby a local diphtheritic tumor was produced at the seat of inoculation, and a general visceral disease; in the cases in which death followed after a few days the lungs were found much congested; when death followed after one or more weeks, the lungs showed broncho-pneumonia, and the kidneys were enlarged and white, the cortex being in a state of fatty degeneration; if the disease in the animals lasted beyond five to seven days both kidneys were found uniformly white in the cortex; if of shorter duration, the fatty degeneration was sometimes only in patches. Although in these experiments the bacillus diphtheriæ was recoverable by cultivation from the diphtheritic tumor at the seat of inoculation, there were no bacilli found in the lung, heart's blood, or kidney, and the conclusion is justified that, just as in the human diphtheria and in the diphtheria produced by subcutaneous inoculation in the guinea-pig, so also in these experimental cats the visceral disease must be a result of the action of a chemical poison produced by the diphtheria bacillus at the seat of inoculation.

From this it is seen that the similarity between the artificial disease and the natural disease in the cat is very great, and the question that presents itself is, In what manner does the animal receive or give the diphtheritic contagium in the natural disease? The natural disease in the cat is, in its symptoms and pathology, a lung disease, and it is reasonable to suppose from analogy that the lung is the organ in which the diphtheritic process in the cat has its seat. The microscopic examination of the diseased lung of cats that died from the natural disease bears this out, the membrane lining the bronchi in the diseased portions of the lobules presenting appearances which in microscopic character coincide with the appearances in the mucous membrane of the human fauces, pharynx, or larynx in diphtheria. But the correctness of the above supposition, that diphtheria has its seat in the lung of the cat naturally diseased, was proved by direct experiment. Broth culture of the bacillus diphtheriæ was introduced into the cavity of the normal trachea without injuring the mucous membrane. The animals became ill with acute pneumonia, and on post-mortem, two to seven days after, there was found extensive pneumonia, and fatty degeneration of the kidney. The bronchi, infundibula, and air cells of the inflamed lobules were found occluded by, and filled with, exudation which, under the microscope, bears a striking resemblance to human diphtheritic membranes, and in the muco-purulent exudation in the large bronchi and trachea the diphtheria bacilli were present in large numbers.

During the last ten or twelve years certain epidemics of diphtheria have occurred which were traced to milk, but the manner in which that milk had become contaminated with the diphtheritic virus could not be demonstrated, although the evidence as to the milk not having been polluted from a human diphtheria case was very strong. The epidemic of diphtheria that prevailed in the north of London in 1878, investigated by Mr. Power for the Local Government Board; then the epidemic that occurred in October, 1886, at York Town and Camberley; the epidemic in Enfield at the beginning of 1888, and in Barking toward the autumn of 1888, were epidemics of this character. Mr. Power, in his report to the Local Government Board on the York Town and Camberley outbreak, states (page 13) that a veterinary surgeon has certified that the cows from whom the infected milk was derived were all in good health, but that two of the cows showed "chaps" on their teats, and he adds that even two or three weeks after the epidemic had come to an end—the use of milk having been in the meanwhile discontinued—he saw at the farm one cow which had suffered chapped teats. At Enfield a veterinary inspector had also certified that the cows were in good health; but at Barking the veterinary inspector found sores and crusts on the udder and teats of the cows.

I have made experiments on milch cows with the diphtheria bacillus, which appear to me to throw a good deal of light on the above outbreaks of diphtheria.

Two milch cows[1] were inoculated with a broth culture of the diphtheria bacillus derived from human diphtheria. In each case a Pravaz syringeful was injected into the subcutaneous and muscular tissue of the left shoulder. On the second and third days there was already noticed a soft but tender swelling in the muscle and the subcutaneous tissue of the left shoulder; this swelling increased from day to day, and reached its maximum about the end of the week; then it gradually became smaller but firm. The temperature of both animals was raised on the second and third day, on which days they left off feeding, but after this became apparently normal. Both animals exhibited a slight cough, beginning with the eighth to tenth day, and this gradually increased. One animal left off feeding and ruminating on the twelfth day, "fell in" considerably, and died in the night from the fourteenth to fifteenth day; the other animal, on the twenty-third to twenty-fourth, left off taking food, "fell in" very much, and was very ill; it was killed on the twenty-fifth day.

In both animals, beginning with the fifth day, there appeared on the skin of the udder, less on the teats, red raised papules, which in a day changed into vesicles, surrounded by a rim of injected skin. The contents of the vesicles was a clear lymph, the skin underneath was much indurated and felt like a nodule; next day the contents of the vesicle had become purulent, *i. e.*, the vesicle had changed into a pustule; in another day the pustule dried into a brownish-black crust, with a sore underneath; this crust became thicker and larger for a couple of days, then became loose, and soon fell off, a dry, healing sore remaining underneath. The whole period of the eruption of papules, leading to vesicles, then to pustules, and then to black crusts which, when falling off, left a healing dry sore behind, occupied from five to seven days. The eruption did not appear in one crop; new papules and vesicles came up on the udder of one cow almost daily between the fifth and eleventh day after inoculation, in the other cow between the sixth and tenth day; the total number of vesicles in the former cow amounted to about twenty-four on the udder, four on the teats; in the latter they were all on the udder, and amounted to eight in all. The size of the vesicles and pustules differed: some were not more than one-eighth of an inch, others larger, up to one-half and three-quarters of an inch in diameter; they had all a rounded outline, some showed a dark center. From one of the above

[1] The cows had been kept under observation previous to the experiment for ten days, and were in all respects perfectly normal.

cows, on the fifth day, milk was received from a healthy teat, having previously thoroughly disinfected the outside of the teat and the milker's hand. From this milk cultivations were made, and it was found that thirty-two colonies of the bacteria bacillus without any contamination were obtained from one cubic centimeter of the milk.

Unlike in the human, in the guinea-pig and in the cat the diphtheria bacillus passed from the seat of inoculation into the system of the cow; this was proved by the demonstration of the diphtheria bacillus in the milk. But also in the eruption on the udder, the presence of the diphtheria bacillus was demonstrated by microscopic specimens, and particularly by experiment. With matter taken from the eruption—vesicles and pustules—of the udder, two calves were inoculated into the skin of the groin; here the same eruption made its appearance: red papules, rapidly becoming vesicular, then pustular, and then became covered with brown-black crusts, which, two or three days after, became loose, and left a dry, healing sore behind. More than that, the calves that showed this eruption after inoculation became affected with severe broncho-pneumonia and with fatty degeneration of the cortex of the kidney. In the two cows above mentioned, on post-mortem examination, both lungs were found highly congested, œdematous, some lobules almost solid with broncho-pneumonia in the upper lobes and the upper portion of the middle or lower lobe respectfully; the plural lymphatics were filled with scrum and blood. Hemorrhages in the pericardium and lymph glands, and necrotic patches were present in the liver. At the seat of inoculation there was, in both cases, a firm tumor consisting, in necrotic diphtheritic change, of the muscular and subcutaneous tissue. In this diphtheritic tumor continuous masses of the diphtheria bacillus were present; their gradual growth into, and destruction of, the muscular fibers could be traced very clearly.

It appears, then, from these observations, that a definite disease can be produced in the cow by the diphtheria bacillus, consisting of a diphtheritic tumor at the seat of inoculation, with copious multiplication of the diphtheria bacillus, a severe pneumonia, and necrotic change in the liver; the contagious nature of the vesicular eruption on the udder and excretion of the diphtheria bacillus in the milk prove that in the cow the bacillus is absorbed as such into the system.

From the diphtheritic tumor by cultivation, pure cultures of the diphtheria bacillus were obtained; a small part removed from the tumor with the point of the platinum wire, and rubbed over the surface of nutrient gelatine or nutrient agar, yielded innumerable colonies of the diphtheria bacillus without any contamination. In cultural characters in plate, streak, and stab cultures, and in cover glass specimens of such cultures, this cow diphtheria bacillus coincided completely with the human diphtheria bacillus; but in sections through the diphtheritic tumor of the cow a remarkable difference was noticed between it and the bacillus from the cultures, inasmuch as in the tissue of the tumor masses of the microbe, both in the necrotic parts, as also where growing into and destroying the muscular fibers, were made up of filaments which in aspect resembled, to a considerable degree, the hyphæ of a mycelial fungus. But that it was really the diphtheria bacillus was proved by culture experiments and by cover-glass specimens. In the latter the transitional forms between typical diphtheria bacillus and long filaments with terminal knob-like swellings, with spherical or oblong granules interspersed here and there in the threads, could be easily ascertained. In the large number of cultivations that were made of the fresh tumor in both cows, the colonies obtained were all of one and the same kind, viz., those of the diphtheria bacillus; no contamination was present in any of the cultivations.

OUR INSANE HOSPITALS.

By A. F. MYERS, M.D.
BLOOMING GLEN, PA.

IN the issue of June 7, page 550, is an article that deserves more than a mere passing notice. Its purport is the advocating of the mode of administration of a few of our State Insane Hospitals—the plan of a physician superintendent who shall be the head of the institution as physician, chief executive officer of the respective boards of trustees, purchasing agent, etc. etc. The intent of the article may be obvious enough to those who have been watching the course of our insane hospitals the last thirty years. But to the unobserving it may be a hint that there is still something silently back of all this.

If any of our hospitals for the insane are on too radical a plan, as referred to in the resolution under consideration, it is the plan that was adopted for a few of our State institutions many years ago, and should be changed at once. New things are not always the best, but it is a fact that a few of our hospitals conducted on the plan of forty years ago, are too radical the wrong way. The intent and purpose of them were considered the best at that time, but years have wrought a change; better ones have been adopted, and the good results have proven them of eminent fitness in every possible way.

Probably none of our State institutions can boast of perfection, yet, in the eyes of the public, some are conducted on better plans than others. By the mode of administration of a few of our insane hospitals organized among the first in this State, the figurehead of the institution is superintendent, physician, chief executive officer of the various boards, purchasing agent and general business manager, a kind of "shot gun prescription like," so to say—a principle that is beset with many dangers by the way.

This plan gives to the head a power that may be conducive to a great amount of good; but, on the other hand, if put in the hands of an unscrupulous man the prospective welfare of the whole institution is bad. The various boards of trustees are under his control, being shorn of their power by delegating to one man their power to act. All the employés must dance to his piping, right or wrong. Many of the subordinate physicians employed by him are young men, full of theory, but lamentably poor in experience; employed for economical reasons, and the unfortunate populace are at his mercy. Oh, what a sad condition of affairs!

For this there is no redress. If a wrong is committed, the attendant keeps silent, and the patient is quieted by subjection. If cruelties occur, and perhaps terminate fatally, the corpse is sent home, or buried there; and with this final act ends all investigation. Inquests are rarely held. Complaints may be made but they will only be carried to the head of the institution, with only one man's sweet will to act upon—the powerless boards to confirm his report that is never made public—and the result is apparent.

But this condition of affairs is all wrong. The various boards of trustees should be an independent

body, with power to act, only subject to the power of the State and the will of the people. Let the public know regularly of its finances; how their money is spent; its progress and management. If money is squandered, let the culprit be discharged at once; if cruelties are committed, let the guilty party be punished according to law. Let no indulgent laws exist, or unlimited privileges be granted to any one. The vesting of unnecessary powers in any one man is never void of danger, even with the best of men. The last decade has fully proven this.

None but the best of physicians should be employed; only as physicians and nothing more. Only such that have had ample experience and been eminently successful in their chosen profession. These unfortunate patients require just this kind of attention. The remuneration should be adequate, so as to command the ablest medical men.

The female department should, by all means, be under competent female supervision. Many of the causes of insanity among females are peculiar to their sex, and should be looked after by physicians of their sex. Is it probable that they will confide their misfortunes or shortcomings to a young male attendant or physician who has not a particle of sympathy with their misfortune? By no means. For humanity's sake, if for no other reason, let our poor unfortunate women have the proper medical attendance. There are many female physicians who are celebrated for their knowledge and skill to care for this class of patients, and should be employed.

A good superintendent, together with a full corps of competent attendants and employés, should be procured to keep the buildings and surroundings in full accord of the requirements and condition of affairs as they should exist at such a place. The buildings should be kept perfectly clean and neat, and the grounds and surrounding scenery in strict harmony with what nature intended it to be. Proper hygienic principles should be carried out to perfection. What a grand opportunity to do much good unto the unfortunate!

Various visiting, charitable and investigating boards, should have the proper privilege of seeing how the institution is conducted. The time of visiting of the various boards should not be known beforehand by any of the employés of the institution. All business transacted by the board of trustees should be open for inspection. Inmates and attendants should have a legitimate means of presenting their grievances to the proper parties, so as to avoid, or correct any injustice done. Visiting by the curious public should be regulated, no improper liberties allowed; yet the public, if properly admitted can do something to elevate the fallen from their sorrowful condition.

There is no attempt at describing an ideal picture, not at all. These ideas are deducted from facts that are still in actual existence. We hope the days of autocratic superintendence of insane hospitals will soon be relegated to the past.

THE pioneer school for male nurses in this country is in connection with the Bellevue Medical College in New York. The Superintendent of this training-school is a woman, Mrs. O. S. Willard, a graduate of the Bellevue School for Women Nurses. Six young women, graduates of the same establishment, give ward instruction to the men, there being, it is said, no male nurses to be found who are competent to this task.

The Polyclinic.

PHILADELPHIA HOSPITAL.

ENDOCARDITIS.[1]

THE first case that I will show you is a child whose temperature is normal, but the child is ill-nourished and weak and somewhat anæmic. On auscultation a loud, harsh murmur is heard over the heart with the systole, seeming to be a mitral murmur, and resembles very much the murmur that is heard in a dilated heart of an adult. You observe that this child is not cyanotic. When you hear a murmur over the auricles of the heart, always be on the lookout for congenital malformation, or a failure of the foramen ovale to close. An open foramen will be attended sooner or later by cyanosis. The oldest case of which I know, in which the foramen did not close, was a girl sixteen years of age. She had to sit up and was almost asphyxiated, and had to be sustained on digitalis and whiskey, with inhalations of oxygen gas. She died some time later, and the diagnosis was confirmed. In an infant as young as this one the symptoms are not so prominent, and its trouble may be endo-, or pericarditis. The trouble is chronic. I think it is endocarditis, but the fact that there is no cyanosis does not preclude an open foramen ovale.—*Davis.*

PNEUMONIA.

A woman, aged thirty-three years, was brought into the hospital in the last stages of her life, and no history could be obtained. The patient was in a dying condition, and physical examination revealed complete solidification in the lower lobe of the lung, and justified the diagnosis of pneumonia. Temperature ranged from 103.5°–101° F., before death.

A few days after the death of the mother, the child, one year old, was taken ill. The mother nursed the child until a few days before she died. The child's temperature was 102° F., and pulse one hundred; respirations thirty-six to forty eight. Physical examination showed pneumonia. Physical signs were well marked; solidification at the apex, with amphoric breathing. The interesting point is this: Is this a case of direct contagion of pneumonia from the mother? If there ever was a case of contagion of pneumonia, this is certainly one. There is a possibility of acute tubercular infection in this child, but the signs are those of pneumonia. It is getting stimulants. The temperature is lower than it was; the child is not fretting and is not cyanosed. While the prognosis is not absolutely hopeless, yet we fear either croupous pneumonia or beginning tuberculosis. If the child has crupous pneumonia, it will get well. If it is tuberculosis, it will die.

[NOTE.—One week later, the child was still living and not much improved. In all probability, it will die; and the post-mortem examination can only confirm the diagnosis.]—*Davis.*

ACUTE PHTHISIS.

The next case is that of a woman well-advanced in pregnancy, who demonstrates some interesting points as to another affection. Her age is twenty years. Her father and mother both died of phthisis. She always considered herself well. Soon after her last menstrual period she began to cough; has night-sweats, and expectorates freely. No pain in the re-

---

[1] Reported by William Blair Stewart, M.D.

gion of her kidney. Urine is acid; specific gravity is one thousand and thirty, and the sediment consists of fine granular casts. No albumen or sugar present. She has a contracted pelvis also. Her general condition is one of acute tuberculosis, complicating pregnancy. We could not hear the fœtal heart-sounds; there is no evidence of diminution in the size of the abdomen, but there is reason to fear that the fœtus is dead. The patient's face is flushed from weakness, and her condition is one of extreme anæmia; she cannot lie on her back without a great deal of suffering. Even in this position, with the patient lying on her side with the legs flexed, I cannot palpate with any degree of satisfaction, on account of the tense abdominal walls and rapid respiration. It is difficult to determine just what course of action to take in this case. Why not induce labor at once?

It is a well known fact that women suffering with tuberculosis have easy labors, as a rule, and can give birth to large-sized children, with little difficulty. The tissues become relaxed, they have good pains and do not suffer much; and this is a practical reason for not inducing labor. Even if we did induce labor, we would not render the tuberculosis any better. It is better to let her go on to full term, and when labor comes on perform craniotomy if it is impossible to deliver with the forceps. Why not resort to Cæsarean section? The fœtus is affected with the tubercular diathesis, in all probability, and it would not be justifiable to further endanger the mother's life by such a procedure. Another new feature has been brought into the case, by the presence of fatty granular casts in the uterine, and this also makes the case more grave. Creasote and alcoholic stimulants, with the very best diet, constitutes her treatment.

Recently I saw some specimens of tubercular infection that have an interesting history.

A Boston family had a child born to them that they had occasion to wean, and for its nourishment they selected the milk of one cow only. The cow was apparently healthy, as was the child. Soon the child began to droop, and, eventually, died of tubercular disease. A second child of the family, fed from the milk of the same cow, is now sick, and will, probably, die with a tubercular infection. This led the family to send the cow's milk to an eminent bacteriologist for examination. Some of the milk was injected subcutaneously under the skin of four rabbits, and three of them are now dead. The cause of death was miliary tuberculosis. Here, then, so far as "seeing is believing" is concerned, we have a direct contagion of tuberculosis from the milk of an infected cow.

The statement has recently been made that tuberculosis is rare in persons who are careful in the use of meat and milk. Tuberculosis may be conveyed from mother to child in the same way. You need not send a person to their grave because they have tuberculosis; but send them early to Colorado, and they may there recover. Do not send a patient away when he is far advanced in tuberculosis, for he will die in spite of all changes. A number of rabbits were inoculated with tuberculosis; one-half were comfortably housed and surrounded by the best hygiene, and recovered; the other half were put in a dark, damp place, with poor hygiene, and all died. Here is a practical lesson.

[NOTE—An unsuccessful effort was made in this case, at a later date, to induce labor, as it was found that to continue would endanger the life of the mother. She is very weak, and her end is about reached, and it has been decided, in the interest of the child, to perform a hasty Cæsarean section, just at the moment the mother dies. As it is, there is a doubt whether the child is living; but it will be given every chance for its life, in case it is alive.]—*Davis.*

MEDICO-CHIRURGICAL COLLEGE AND HOSPITAL.

FIRST FIVE YEARS' REPORT OF THE EYE CLINIC.

ON the reorganization of the Medico-Chirurgical College in 1884, it was necessary to open clinics for the purpose of getting material for practical teaching and demonstration to the students who might attend. With this point in view, in December of that year, I arranged a small room on the third floor of the building southwest corner Market and Broad streets, where the college was located at that time. At the same time general clinics were opened in another room; but no hospital accommodations were furnished, for want of proper places and conveniences. After some time the hospital was organized, and two large rooms in the building were fitted up for patients, but unfortunately none with the proper accommodations for eye diseases; so that it was not until after the college and hospital were removed, in 1888, to the present locality on Cherry street, between Seventeenth and Eighteenth streets, that the proper conveniences for the admission of eye patients undergoing operation could be afforded, especially admittance into wards, alone and away from other diseases and operations, which could not be had until last year; so that really operations of cataract, iridectomy, etc., were mostly made during that time.

In a large city where there are many hospitals and clinics already established, it is no easy matter to build up new ones, at once affording material enough for teaching, but whether from the locality or some other causes, there seems to have been a large increasing attendance from the first opening of all the departments in connection with this hospital, which is seen by the general reports of the institution.

In the eye clinic, during the past five years, that is from the opening in December, 1884, to December, 1889, 3,247 cases were treated, classified as follows: Affections of the lids and eye-brows, 290; lachrymal apparatus, 89; conjunctiva, 317; cornea and sclerotic, 387; crystalline lens, 148; iris and ciliary body, 87; choroid and vitreous, 89; retina and optic nerve, 78; eye-ball, 31; orbit and vicinity, 4; muscular and nervous system, 175; anomalies of refraction and accommodation, 1,452. Total, 3,247.

The number of operations performed before the class of students was 368; as follows: Cataract, 44; iridectomy, 15; abscission of the cornea, 1; enucleation of eye balls, 29; cornea and conjunctiva, 124; lachrymal apparatus, 39; lids and eyebrows, 68; muscles, 40; orbit and vicinity, 2; evisceration or exenteration of eye-ball, 6.

During the summer of 1889 a series of dispensary rooms was made to accommodate the different departments for the reception and treatment of the various medical and surgical diseases that present themselves, and in this arrangement increased facilities have been given for the eye department, and the daily attendance has been steadily increasing.—*Keyser.*

PICHI was introduced as a remedy for cystitis. Rusby (*Med. Record*) quotes a number of reports upon the drug, showing it to be of special value in acute cystitis occurring with childbirth, surgical operations, nephritis or gonorrhœa. In chronic cystitis it gave relief; it proved useful as an antilithic, but failed as a lithontriptic.

The Times and Register

A Weekly Journal of Medicine and Surgery.

New York and Philadelphia, July 19, 1890.

WILLIAM F. WAUGH, A.M., M.D., Managing Editor.

THE TIMES AND REGISTER,

REPRESENTING THE

PHILADELPHIA MEDICAL TIMES.
THE MEDICAL REGISTER.
THE POLYCLINIC.
THE AMERICAN MEDICAL DIGEST.

PUBLISHED UNDER THE AUSPICES OF THE

AMERICAN MEDICAL PRESS ASSOCIATION,

Address all communications to THE MEDICAL PRESS COMPANY, LIMITED, 1725 Arch Street, Philadelphia.

THERE is a serious split in the eclectic ranks in Indianapolis. The State Medical Association has repudiated the college which, according to the *Free Lance*, has fallen into the hands of one W. P. Adkinson. This personage secured a controlling interest in the capital stock of the college, elected a board of his own choice, and got this board to confer on him the degree of Doctor of Medicine. This action is said to have been illegal, as the charter limited each holder of stock to a single vote; irrespective of the number of shares held. For these reasons the Indiana Eclectic State Medical Society repudiates the Medical College, and the eclectic journal follows suit; and every one honors them for the manly stand they have taken.

The history of eclecticism is peculiar. It arose from a reaction against the excessive use of depressants; the elements of its popularity are to be found in the natural dislike of our people to uniformity in belief and practice, the plea that our native drugs were neglected for the imported articles to whose use the profession was habituated, and the encouragement the system gave to that home medication so dear to the housewife's heart. Each of these exerted an influence favoring the popularity of eclecticism.

Americans dislike uniformity. We are never satisfied with a good thing, beause we think there is a better. England treats dysentery with lead and opium, just as she did a century ago; we have a new remedy every season; just as we have a new religious sect or political heresy. And no scheme, religious, politics or medical, can be broached here which does not win a following respectable in numbers.

As to the second element there was, besides the impulse of patriotism, a certain plausibility in the idea that between the diseases of a country and its remedial plants there was such a relation that the latter would be specially curative of the former. There is no doubt whatever, that we did neglect our native medical plants, and that we have not even yet given them the attention they merit.

The preparation of "teas" has always been popular with women, whose tender hearts impel them to be actively engaged in "doing something" to relieve the sufferings of the afflicted. The villainous decoctions of the Thomsonian, however, have given place to a valuable line of preparations, the powdered extracts; which are to-day well worth the attention of the profession. They have the convenience of the alkaloids, while better representing the full medicinal virtues of the plant.

The remedies employed by eclectics differ from those of our homœopathic brethren in that the former have really efficient drugs, producing effects quite as decided as those of the mineral salts. So far as it goes, then, the eclectic practice is a true and legitimate one; and the only fault we can find with their system is the limitation of their therapeutics to vegetable remedies, instead of extending it to embrace *all* that can assist in bringing health to the patient.

But in its practical workings another very serious objection is to be urged against that school, in that from it have sprung nearly all those notorious venders of bogus diplomas who have brought such disgrace upon the name of American medicine. The founders of the school not being educated physicians, it was natural that they should not set much importance upon the possession of what Hahnemann calls "the lore of the medical schools," and which, as an educated physician himself, he particularly urges his followers to acquire. The Buchanans, Paynes, etcetera, assumed the cloak of eclecticism; the Philadelphia Eclectic Colleges left such a stink in the public nostrils that no school of that sect could exist here. And now the Indiana College, with a Dean whose medical degree has just been voted him by a board elected by himself, as principal owner of the school, is not likely to pursue a very different course. But there are good men in eclecticism, as shown by the action of the Indiana Society; men whose qualities give strength to a system which would otherwise disappear; as the profession realizes the value of the eclectic preparations, and the eclectic is educated out of his narrow limits. If the Association of American Medical Colleges next summer decides to admit the graduates of eclectic colleges to the graduating classes of our own schools, provided they can pass the same examinations required of our own second-year students, the separate existence of that sect will be short lived.

Annotations.

FOR the treatment of gout, Rademaker (*American Pract and News*) claims specific virtues for a combination of colchicine, decandrine, and solanine, with potassium iodide; the alkaloids neutralized with hydriodic acid and sodium salicylate added. This is made into an elixir and denominated "solution of triple hydriodates, with salicylate of soda."

The name is objectionable, in that it does not give any hint of the presence of three very active alkaloids; none of them safe if taken incautiously, or of the iodide of potassium, which surely deserves recognition as well as the salicylic salt; especially as the author is compelled to caution the reader against the tendency of the preparation to produce iodism. How would this answer: "Compound iodo-salicylated colchicine elixir?"

SUIT has been entered to restrain the city from closing up the Wingohocking creek, by the owner of a mill that uses the water for power. This creek has long been an open sewer, which in some parts of its course threatens the health of Germantown. Part of the stream is covered by a culvert; and at the point where this culvert ends, diphtheria and kindred diseases prevail to a greater extent than over any other part of the course of the stream. It would seem as if the free diffusion of exhalations were less apt to be dangerous than those which are confined by the culvert and find exit at one point. The indication is to cover in the exposed portions of the stream, and provide for the ventilation of the whole culvert. Partial closure is worse than none at all.

SPASMODIC torticollis is rarely more than temporarily benefited by surgical measures, but Mayo Collier, in *The Lancet*, relates a more fortunate case. A girl of twenty-one years, with extreme torticollis of six years' standing. The head was severely rotated far to the right every few seconds, continuing with less violence during sleep. She had been dosed with drugs innumerable, galvanized, blistered, tonsils removed, galvano-cautery applied to back of throat, with no good effect.

The spinal accessory nerve was found, and followed into the sterno-mastoid some distance, using moderate traction on the nerve, but avoiding injury to the muscle. A loop of silver wire was placed around the nerve, as far up as possible, just twisting the ends to insure slight compression. The ends of the loop were left protruding from the wound. On emerging from the anæsthesia the spasms had ceased, and have never appeared since. The ends of the wire were cut close to allow the skin to grow over them.

STROPHANTHUS has been investigated by Bucquoy, whose conclusions are, in the main, confirmatory of those of Frazer. The drug is indicated by ventricular incompetence. It increases the ventricular force and lessens the pulse, but does not contract the arteries like digitalis. Strophanthus acts best in aortic valve disease, as the increased ventricular force is better shown here than when partly lost through mitral insufficiency. As in aortic diseases, there may be no compensatory hypertrophy. Strophanthus here occupies just the gap left by digitalis, as the latter has long been distrusted in aortic cases.

Strophanthus is said to be of less permanence as to its effects than digitalis. Clinical observation appears to show that the new drug is less decided in its action. The indications for its use are, however, so sharply differentiated from those of digitalis, that with comparative uniformity in the quality of the preparations to be found in pharmacies, strophanthus ought to supersede digitalis in nearly all cases, except when a hemostatic effect is desired, or the certain and rapid action of digitalis is needed in emergencies.

Letters to the Editor.

COAL OIL.

COAL oil has quite a reputation as a remedy in intussusception and fecal impaction. I have only used it in the former affection. We know that, mechanically, this oil is quite searching and penetrating. Just how it acts in intussusception, I am not prepared to say. It is my opinion, however, that its action is mechanical; working its way along the folds of invaginated and inflammed bowel, perhaps carefully breaking up the products of inflammation, and being gently moved on by the volume of water behind, the displaced portion of the bowel floats to its normal position. To illustrate roughly, call to mind a flock of sheep; "one go, all go." I fail to see where anything is gained by passing a tube into the bowels. For, unless the tube is passed well into the transverse colon, or the hips well elevated, the water will follow the tube back and the flushing must begin at the sphincter. I placed my patient in the knee and breast position, where he easily took one pint of coal oil followed by four pints of warm water. He was then directed to lie on his right side and retain the injection as long as possible. This was repeated every four hours. Patient made a good recovey.

GEO. CHAFFEE, M.D.,
1047 Third Avenue, Brooklyn.

HONOR WHERE DUE.

I AM in receipt of a sample copy of THE TIMES AND REGISTER, dated July 15, 1890, which contains a summary of the proceedings of the Ohio State Medical Society. In this summary there are remarks reported as made by myself concerning the use of chloroform in labor. Now, while I am in accord with those remarks made in the discussion of Dr. J. F. Baldwin's paper on The More Frequent Use of Chloroform in Obstetrics, yet I did not make them. They were offered by Dr. C. B. Ferrell, of 78 South Third St., Columbus, O. "Honor to whom," etc.

W. W. PENNELL.

Book Reviews.

HOW TO PRESERVE HEALTH. By LOUIS BARKAM, M.D. New York, 1890. Cloth. Pp. 344. Price, $1.00.

A question of the first importance, and one that we should always be ready to give advice upon.

TRANSACTIONS OF THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION. Volume II. Second Session, held at Nashville, Tenn., Nov. 12, 13, and 14, 1889. Published by the Association, 1890.

The volume contains papers by Maury, Roberts, Hardon, Haggard, Wathen, Johnstone, J. Price, Robinson, Engelmann, Davis, Brokaw, Hadra, McMurtry, Douglas, Lydston, Stone, Browne, Meriwether, Mathews, Nicholson, Kollock, Goggans, Claiborne, McRae, Lapthorn Smith, Briggs and Johnson.

RHEUMATISM AND GOUT. By F. LEROY SATTERLEE, M.D., Ph.D. Detroit, Mich.: George S. Davis. Pp. 83. Cloth, 50c.; paper, 25c.

Dr. Satterlee tells us that he has himself suffered from the ailments which he describes. This renders the book of special value, as it is not often we get one written under such circumstances.

In acute rheumatism he lays much stress upon the use of cholagogues, giving the following formula:

℞.—Euonymin . . . . . gr. ¼
Podophyllin . . . . . gr. ⅛
Aloin . . . . . gr. ⅛
M. S.—One tablet twice daily, as required.

He objects to the salicylates on grounds which show a very exceptional experience or a no less exceptional lack of skill in their use on his part. His preference is for the alkalies, which he gives in the following forms:

℞.—Potassii bicarb. . . . . ʒij–ℨij
Aquæ destillat. . . . . fʒviij

M. S.—One fluidounce to half an ounce of fresh lemon-juice; to be taken while effervescing.

℞.—Lithii benzoat. . . . . ʒss
Sodii bromid.,
Potassii carbonat. pura. . . . . āā ʒij
Potassii acetat. . . . . ℨiss
Sodii phosphat. . . . . ʒss.
Syr. zingiberis,
Aq. menth. pip . . . . . āā ad ʒvj

M. et Sig.—fʒij to fʒss, in half a glass of water, every four or six hours, after food.

He states that this mixture of three bases combined with five acids is effectual and agrees well with the stomach.

In *Zeitschrift für Physiologische Chemie*, Vol. XIV, No. 5, Trasaburo Araki, of Strassburg, "On the Coloring Matter of the Blood and its Derivatives," shows that the usual spectroscopic characters of methæmoglobin are deceptive and due to the presence of other substances especially oxyhæmoglobin, and that true spectra cannot be obtained of this substance so long as the solutions are either acid or neutral in reaction. In pure methæmoglobin solutions, the band in the green almost disappears, while that in the red becomes more developed. Some further researches on sulphur-methæmoglobin are given, and its identity with the green color of decomposing flesh is noted.

Dr. Herm. Karl Ludwig Baas, of Worms, discusses the changes of fats in the alimentary canal.

Paul Manasse, of Berlin, contributes "On the Lecithin and Cholesterin of the Red Blood Corpuscles." He cites the experiments from 1846 to the present time, of, in the order named, Gobley, Fremey, Liebreich, Parke, Hoppe-Seyler, and Dinkonow, who, collectively, had succeeded in demonstrating the existence of these substances, in yolk of egg, ova of fish, brain substance, bile and the red blood corpuscles, but, owing to the difficulty of isolation, their chemical identity had not been clearly established. By a series of experiments, faithfully detailed in the article, he claims to have settled this question.

Fredrick Reinitzer, "On the True Nature of Germ Ferments," deals with a question related principally to vegetable physiology, and, therefore, not of direct concern to the medical man.

"A Contribution to the Chemistry of Horny Matters," by Prof. E. Salkowski, of Berlin, based on a series of experiments, in which the professor was assisted by Dr. Ken Taniguti, of Japan, and looking to the physiological and chemical rôle of kreatinin, ends the number.—Samuel Wolfe, M.D.

Pamphlets.

Climatology and Diseases of Southern California. By F. D. Bullard, A.M., M.D. Reprinted from the *Southern California Practitioner.*

Ordinances of the City of Leavenworth, Kansas, relating to the Preservation of the Public Health. Compiled by C. F. W. Dassler, City Attorney, and W. D. Bidwell, M.D., Secretary of the City Board of Health. June, 1890. Leavenworth, Kan.: Ketheson & Reeves, Printers and Engravers.

Judging from these ordinances, the Kansas town gives a heed to its sanatory advisors that some older communities would do well to imitate.

WOULD you rather belong to a family noted for long heads or for long livers?

The Medical Digest.

LOVIOT has described a case in which an intestinal calculus, the size of a small orange, was produced by the immoderate use of Vichy salts.

ANALYSIS of Armour's meat extract shows it to consist of 68 per cent. water, 20 nitrogenous extractives, and 12 salts. This is a much greater proportion of water than is contained in Liebig's extract.
—*Brit. Med. Journ.*

PLENCKII'S SOLUTION, for cauterizing condylomata:

Hydrarg. chlor. corros.,
Aluminis,
Cerussæ,
Camphoræ,
Alcohol,
Aceti vini . . . . . āā partes equales.

HYPERTROPHY of the Schneiderian membrane, causing asthma, etc., is treated by spraying the following solution:

℞.—Antipyrin . . . . . ʒ j
Cocain. mur . . . . . gr. xx
Aquæ . . . . . ʒ iv. M.

—Potter, *West. Reporter.*

HUZZA (*Dixie Doctor*) reports a case of hematuria in which he gave the tincture of carduus marianus, in drachm doses thrice daily for two months. The case was that of a man sixty years old. The hematuria came on suddenly, following a lascivious dream. Over a pint of blood was estimated to be passed daily. The blood gradually diminished, and finally disappeared; though it recurred after violent exertion.

BIRCH BEER.—This pleasant and wholesome summer drink may be made by the following formula, from the *Pharm. Era:*

Birch essence . . . . . 1 ounce.
Wintergreen essence . . . . . ¼ "
Sassafras essence . . . . . ¼ "
Ground cinnamon. . . . . 1 teaspoonful.
Hops . . . . . 1 teacupful.
Water . . . . . q. s. to 1 gallon.

Steep ten hours; add sugar or molasses to taste, and one cup of baker's yeast. It is then ready for bottling. The essences are merely strong infusions.

BEACH (*Brooklyn Med. Jour.*) mentions a case in which a series of abscesses occurred on the ear, in the temporal region, the scalp, hand, etc. Attention was finally attracted to a sinus leading to the roof of a dead tooth. It was noticed that when this sinus closed the abscesses appeared. The tooth was extracted and the abscesses ceased to appear.

Cases of general ill-health, sometimes quite serious in degree, have been known to resist every mode of treatment until decayed teeth were extracted. Sometimes the speedy return to health is remarkable. In one case, the only assignable cause for amyloid liver and kidneys was necrosis of the teeth, in a child four years of age.

CHROMIC ACID IN CYSTS.—Woakes (*Lancet*) advocates the use of chromic acid in the treatment of cysts of various sorts. In a case of cystic goitre, where the cyst had refilled after evacuation and tannic acid injection, and a sinus had formed, he

passed a probe dipped in a saturated chromic solution into the cyst cavity. This was done repeatedly for three weeks, and five weeks later the cyst-wall came away entire.

In the second case, one similar to the first, the acid was applied to the walls by means of the "acid carrier." At the end of a week adhesion of the cyst-walls was complete.

In the third case the cyst was tapped and emptied, and the acid at once applied directly to the cyst-wall by the carrier. Rapid recovery ensued.

A fourth case presented two cysts. One of them bled freely on being tapped, and the blood neutralized the acid so that a second application was required to cure.

A case of ranula is also described, in which the application of the acid brought about a rapid cure.

AGGRAVATED HEMORRHOIDS.—1. In the more aggravated forms of hemorrhoidal disease the surgeon has to do with a veritable angeioma, sometimes involving the whole circumference of the anal end of the rectum.

2. The anatomical relations of this vascular tumor are such as to render possible its enucleation and ablation without special hazard to life, and without involving especially difficult operative procedures. This has been demonstrated on a large scale by Mr. Whitehead, of Manchester, England, and is corroborated by the experience of many other surgeons.

3. The method of excision and suture is inherently a more desirable operation than other methods involving strangulation of tissue, ulcerative and suppurative processes. It is not, however, so easy or so quick of performance, and demands a greater degree of technical skill and experience for its safe employment.

4. The best final results from the operation can only be obtained by avoiding injury to the sphincter muscle, or to its nerves; by the preservation of all the integument at the verge of the anus, and by the even circular discission of the rectal mucous membrane above the growth.

The operation of excision though, in the more aggravated cases of hemorrhoidal tumors, often tedious and bloody, presents no difficulties not under the easy control of ordinary surgical skill; its results are superior to those obtainable by any other means; it is, therefore, an operation to be commended, and to be accepted as a permanent addition to the art of surgery.—Pilcher, *Brooklyn Med. Jour.*

WHEN shall we use hypnotics? In acute disease, particularly fevers, sleep is often a necessity, reducing the activity of the heart, removing more waste, and quieting the general excitability of the nervous system. In chronic disease there is frequently the same temporary need. In incurable disorders with pain and discomfort, in the restlessness of senility, hypnotics and narcotics—and used freely in the last years of life—are almost the chief justification of our service. Often in mental disease they are, for a time, all but indispensable. In some neurotic people their occasional use can hardly be avoided. In acute nervous and mental disturbance from profound shock, full and continued doses of narcotics may dispel most threatening symptoms. The individual must, of course, be taken into consideration. Many can be depended upon to use hypnotics only as directed by their physician; others can no more be trusted with them than certain persons with alcohol. Something of slight intrinsic hypnotic value may be intensified by its mental effect, and I am sometimes deliberately asked for a prescription upon which to build a mind-cure. It is often imperative to prescribe a hypnotic, where it is best that a decided hypnotic effect should not be got. For this purpose a somewhat unpleasant drug is better than an altogether agreeable one, and the prescription which I use consists of a few minims of paraldehyde in a drachm of chloroform water. This can be repeated in the night several times, and be continued without harm.

In some conditions, even with acute maniacal symptoms, it is better to let the patient lie awake almost absolutely for two or three nights than give the amount of narcotics necessary to produce sleep.

—Folsom, *Boston Med. and Surg. Jour.*

SUMMER DRINKS IN INDIA.—The *Medical Record* of Calcutta contains some interesting remarks upon the beneficial effects to be derived from non-alcoholic drinks in the height of summer. After remarking that the very bane of European existence in India lies in the habits of eating and drinking, physiological arguments are adduced to show that highly carbonized materials are very deleterious in hot climates. The custom of the Moguls, who for luxury have had no equal in Indian history, is referred to as offering a fitting example. Their drinks consisted of milk, sweetened waters, or sherbets, prepared from subacid fruits, such as lemons, tamarinds, pomegranates, etc., flavoured with rose or Keora essences, date juice, numerous vegetable tisanes, and some infusions of glutinous seeds flavored with sugar and essential oils. These were often cooled with ice collected in pits, where it was stored during the winter months. The Oriental races, it is asserted, suffer from few of the diseases which are common to the copious meat-eating, wine-drinking Europeans. For a hot day, a light vegetable diet is recommended, with a spare quantity of meat food, and an abundance of cooling, non-alcoholic drinks. Ice is regarded as a necessity, and coffee, tea, and cocoa are to take the place of whiskey-and-soda. The use of ærated waters, prepared from pure and wholesome ingredients, and the admixture in them of the numerous fruit flavorings which abound in the tropics, are regarded with favor, as likely to offer a lucrative source of income to persons engaged in such trade, while also giving the European community a very acceptable form of summer drinks. This suggestion has already, to a certain extent, been put into practice both in this country and in America, but there is still some uneasiness as to possible evil consequences resulting from the consumption of large quantities of iced drinks when the atmospheric temperature is high. As regards light diet and extreme moderation in the use of alcohol, however, the recommendations are admirable, and might well be followed here.—*Lancet.*

OVARIAN HERNIÆ.—THEIR CAUSES, SYMPTOMS, AND TREATMENT.[1]—Ovarian herniæ are amongst the most neglected, although clinically they should be included amongst the most important, of the troubles that come before us in gynecological practice. In the great majority of cases they occur downward into Douglas' space, and in such instances the left ovary is that most frequently displaced. The next in point of frequency of these herniæ are those occurring in the inguinal regions, where they are either

[1] Abstract of a paper read at the British Medical Association, Annual Meeting, Birmingham, July, 1890—Obstetric Section.

found above Poupart's ligament or, as is more commonly the case, follow the course of the canal of Nuck downward and forward, and so present in the labia, where they may be readily recognized. In the former or directly downward variety of displacement, the ovary may be discovered on vaginal examination in the recto-vaginal fossa as a small, oval-shaped, firm, elastic, and highly-sensitive tumor, bulging forward into the post-cervical *cul de sac.* In the larger number of cases ovarian herniæ, especially those in Douglas' space, result from the *vis a tergo* of abdominal or uterine tumors, or from the tension on the appendages occasioned by displacements of the uterus.

Diagnosis.—Until recently these herniæ, when inguinal, were very generally compounded with en larged glands; when labial, with other tumors in that situation, and when downward, with pelvic abscess and hematocele. Or, as often happens, they are mistaken for the retroflexed fundus uteri, and the patient, suffering from an ovarian prolapse, is vainly treated for a non-existent retroflexion or retroversion of the uterus. There can now be no excuse for such errors. The sudden occurrence of the tumor, its physical character, the peculiar dull, sickening pain, and the extreme tenderness and nausea manifest on examination, are sufficient to enable a correct diagnosis to be made by any competent gynecologist.

Treatment.—Where the ovarian herniæ take place through either of the abdominal rings or downward into Douglas' space, it may, in some instances, be reduced as any other hernia similarly situated. In the majority of cases, however, such herniæ are irreducible when discovered, and must either be supported in the former case by applying a hollow truss, whilst in the latter case the prolapsed ovary must be replaced, if possible, and kept in position with a peculiar form of pessary, exhibited, specially devised by Dr. More Madden for the purpose; or, failing this, if the symptoms be urgent, the ovary must, in some cases, be removed.

The foregoing views are illustrated in the paper of which this is an abstract by the details of several instances of ovarian herniæ, exemplifying the clinical history and treatment of such cases.

—Thomas More Madden.

PLASTER SPLINTS FOR FRACTURES OF THE LEG.—The form of splint which I am about to describe has been found to be particularly convenient for dealing with such fractures of the leg as are suitable for the "immediate" method of treatment. In the case of a fracture—say at the junction of the middle and lowest thirds of the leg—three measurements are taken: (1) The length of the limb from an inch and a half above the knee to the sole of the foot; (2) the circumference of the thigh at the level of about an inch and a half above the knee; (3) the length of the foot from the heel to the ball of the big toe. An oblong piece of old blanket is then cut out, one way an inch and a quarter longer than 1, the other way an inch and a half less than twice the measurement of 2. The limb is laid on the flannel, which is held up by its edges, supporting the leg as in a sling. Next the flannel is tacked together close to the limb, down the front of the leg, along the sole, and then along the dorsum of the foot. It is better to sew the flannel up in the order given, along the sole first and along the dorsum afterwards, because by doing so the foot will be held by the flannel in the position in which it should be—at a right angle with the axis of the limb. The leg is thus closely encased in flannel; whilst, along the front of the leg and dorsum and sole of foot, a double free edge of flannel of greater or less extent is left beyond the seam. These free edges along the dorsum of the foot, as high as the ankle, and along the sole, are trimmed off close to the seam. There now remain two considerable wings of flannel, extending down the front of the leg as far as the ankle. Each wing, when turned back from the middle line in front, will reach to within about half an inch of the middle line behind. These wings are then trimmed from below upward, so as to shape them to the form of the leg. Two side splints, with rectangular foot-pieces, are then cut out of flannel, similar in shape to those used in a "Croft." They are cut out so that each piece, when applied to the limb, shall reach to within about a quarter of an inch of the middle lines in front and behind. Care must be taken that the anterior edge of each side-piece is quite straight; the posterior edge may be shaped so as to allow for the swelling of the calf muscles. Traction is then applied to the limb, and these side-pieces, having been thoroughly saturated with plaster-of-Paris solution, are placed over the flannel casing, one on each side of the leg. The wings of flannel are then quickly folded back, each over its respective side piece, and smoothed down. Some plaster solution is then rubbed well into the outer surface of the two flannel wings, avoiding, however, a border about a quarter of an inch wide and extending down the front of the leg, on either side of the seam. The perfect adaptation of the splint to the limbs may then be secured by applying a thin muslin roller bandage over the whole from the toes upward. After ten minutes, the muslin bandage is unrolled, and the splint is then finished. The plaster will probably be quite dry in the course of an hour or so. When the splint is completed, it will be seen that, next to the skin, there is a continuous casing of flannel; that, outside this, there is on either side, except just below the ankle, a double thickness of plaster-saturated flannel; that along the middle line behind there is a sort of hinge formed by the single thickness of plaster-free flannel of the original casing, and that each anterior edge, when the splint is opened, is formed by a fold of soft flannel. This latter is of importance, as the skin is thereby protected from uncomfortable pressure of the anterior edges of the plaster-saturated side-pieces. Thus, with these splints, there is no tendency to the formation of superficial bullæ from this cause, nor will subsequent padding with cotton-wool be found necessary.

—Fouleiton, in *The Lancet.*

SPANISH TRANSLATIONS.

DR. W. F. HUTCHINSON.

From "La Cronica Medico-Quirurgica de la Habana."

The Commission chosen by the Society of Clinical Study, at the session of the 11th of last February, whose duty it was to look up all possible information relative to the fever known as "fiebre de borras" (climate or weather fever) have sent to all practitioners on the island a list of questions, answers to which will constitute a pretty complete study of the disease. It seems especially desirable that the nativity of this fever should be ascertained, as it and those of its class appear to belong to tropical islands by preference.

The Society has issued the following circular:

Among the diseases that are peculiar to the country and whose origin is still unknown is this "fiebre de borras," regarded by some as an entity, and by others as a modification of the yellow fever poison in natives.

This fever, of frequent occurrence at certain times of the year and in certain well determined localities, is of doubtful nativity.

For this and for other reasons, it was included in the programme of the first Cuban medical congress, where its consideration evoked a lively and interesting discussion.

Following one of the recommendations of the congress, the Clinical Society trusts that the committee to be appointed will promptly proceed to obtain all possible information on the subject, and to this end have formulated a series of questions, answers to which will probably give all necessary light upon the subject.

In order to give sufficient time to arrange these, or to gather new facts, the investigation will not close before the 30th of September, 1891, at which date all replies are to be in the hands of the Secretary.

The questions are prepared with great care, and will doubtless give excellent results.

ILLUSTRATIONS OF SOME LESS-KNOWN FORMS OF PERIPHERAL NEURITIS, ESPECIALLY ALCOHOLIC MONOPLEGIA, AND DIABETIC NEURITIS (Thomas Buzzard, M.D., F.R.C.P.)—As is now widely known, it is in the form of multiple neuritis that the toxic influence of alcohol is very prone to be exerted on the nervous system. Cases of alcoholic paralysis of this kind are not at all uncommon, and occur more frequently in women than in men, and occasionally even in females of good social position.

Let me first very briefly sketch a case of alcoholic polyneuritis as it most commonly presents itself when seen in consultation.

The patient is lying in bed, unable to stand; able to flex the thighs upon the pelvis fairly well, and possibly also to bend the knees, but with still greater difficulty. The feet are "dropped," that is, they lie flaccidly in a position of over-extension, and the patient is unable, when requested, to dorsal-flex them. The knee-jerks are absent. The muscles of the legs, especially those on the anterior surface below the knee, are probably atrophied, and are found to yield no response to induced currents of electricity. The arms are thin, and the thenar and hypothenar eminence may be found atrophied. There is more or less "wrist drop," so that the patient presents the appearance of one suffering from lead palsy. The extensor muscles in the forearm, as well as the intrinsic muscles of the hand, may not contract to faradic currents.

On the sensory side we may expect to hear of pains, which are often of lightning character, coming and going in sudden darts, like stabs of a knife, or the boring of a gimlet, and quite recalling those which are characteristic of tabes dorsalis. Or they may be described as gnawing, or burning, or pricking. They are usually most pronounced in the lower extremities. It is commonly found that great tenderness of the muscles is complained of when these are grasped by the hand. The patient herself will sometimes describe a sensation of aching in the muscles, and very commonly, indeed, a feeling of "numbness," "deadness," or "pins and needles," which is referred especially to the hands and feet. More or less cutaneous anæsthesia is found in the feet and legs. As a general rule the functions of the bladder are not disordered, and there is no tendency to bedsores.

There is usually a remarkable loss of memory, the patient often saying, for instance, that she has been out for a walk on that day, when she has not left her room for many weeks. There is often also a condition as though of complacent indifference and incapability of grasping the full meaning of her condition, which seems to be peculiar to a state of chronic alcoholism.

If such a case as this should give the opportunity of post-mortem examination (a comparatively rare exception) a subacute inflammatory process will be found affecting the nerve trunks, especially the radial and anterior tibial or the peroneal. The nerves will seldom show any particular change to the naked eye, but, having been hardened and submitted to section, evidence of parenchymatous degeneration is discovered in them, together with more or less interstitial neuritis.

In females affected with alcoholic neuritis I have observed now, during many years, that the catamenia are almost suppressed, and often for many months during the illness. I do not attempt an explanation of this. It seems to me a curious and interesting fact when taken in conjunction with the well-known complete, or almost complete, immunity of the functions of the bladder and rectum.

Although in the majority of cases it is the nerves of the extremities which appear to bear the brunt of the lesion, yet I have seen paralysis of the respiratory muscles and of those subserving degultition, and in one instance almost complete paralysis of the external muscles of the eyeballs. The pneumonia which occasionally terminates the scene in cases of this kind is very likely due to lesion of the vagus.

I have given an illustration of the more usual symptoms in a case of multiple neuritis due to alcohol. It is necessary to mention exceptional conditions which are found in certain cases. There may be no pains, and but very little or indeed no disturbance of cutaneous sensibility. It seems that in some rare instances it is almost entirely the efferent fibres which suffer. There is often a very considerable amount of œdema of the feet and legs, and the hands may look puffy and sodden. Indeed, I have seen one case in which the brunt of the lesion appeared to fall mostly on the vasomotor system of nerves, and give rise to œdema. In some cases it is chiefly a tottering ataxic gait, which is noticeable. This often precedes the paralytic state, which may and often does arrive quite suddenly.

Although a drop condition of the feet is so common as to be highly characteristic of alcoholic paralysis, and should always suggest inquiries into the history, yet I have lately seen a few cases in which the symptom was not present. In these, it is true, the amount of paralysis of the lower extremities was not very great, but as the loss of power in the anterior tibial muscles is commonly an initiatory as well as a very characteristic symptom, it seems worth while to note that it may occasionally fail to occur, at least early in the case.

A case which I have seen this winter illustrates some of these exceptional conditions. A gentleman who had greatly exceeded began in September to lose power in the knees and ankles, at the same time complaining of pains in the muscles of his legs. He managed to attend office for a month, then one day, when dressed and ready to start, his legs gave way under him and he could not get up. He then began to lose power in the hands, which swelled and were numbed. They remained bad for a short time only. When I saw him two months after his attack he had not been able to walk, or even to stand. His legs were swollen, he could not dorsal-flex the feet. There were no pains, nor anæsthesia, nor tenderness of muscles. The knee jerks were absent. He made a rapid

recovery, and in three months was almost well. When I last saw him both knee jerks had returned.

The lower extremities as a rule are more severely affected than the upper. It occasionally happens, however, that when the patient comes under observation recovery has taken place in all except one limb, and then there is a chance, unless care be taken, of a mistake in the diagnosis of the case. A lady was seen by me, in consultation, in April, 1888. She was suffering from loss of power in the left hand. She had no complaint to make of her legs, or of the right arm. There was wasting of the thenar and hypothenar muscles of the left hand, with loss of faradic reaction. The skin was red and polished looking. The catamenia had been absent for some months.

There was exquisite sensitiveness to touch at the tips of the fingers and in the palm, and if the wrist-joint were moved it caused her excruciating pain. The hand and arm presented the helpless look of a fractured limb. The fingers were white and puffy, the nails overgrown, because she could not bear to have them cut. Great tenderness was experienced on pressing the median nerve at the wrist. The right thumb, and two fingers were sensitive at the tip, and the hand was weak; it had been still more helpless than when I saw it.

In January the patient had begun to feel as if she had "rheumatism," and her fingers became oversensitive. At that time she was very weak.

In February her knees would give way, so that she fell more than once on her wrists. At that time she was walking with the help of a stick or some one's arm, on account of "rheumatism" in her knees. She dragged her feet. She was treated with induced electrical currents, and the hands gradually improved.

On May 3d, after the hand had been placed in hot water for the purpose of faradism, it became purplish-red and swollen. I have often noticed this to happen in cases of neuritis. The cuticle will often scale off.

On May 26th, adhesions in the wrist and finger-joints were broken down under chloroform. Under faradism, massage, and passive movements she slowly improved, and I heard subsequently that the arms had got quite well. It should be said that there was a distinct history of excessive drinking in this case.

In the following case neuritis (presumably from alcohol) was confined from the first to the district of a single muscle.

A gentleman, aged twenty-nine, was sent to me by his medical attendant with paralysis of the index, middle, and, to a less extent, of the ring finger of the right hand, which had been observed for three weeks. The patient was a paroxysmal drinker, and had just come out of a debauch of several weeks. The hand presented just the appearance of an early stage of wrist-drop from lead. There was no blue line, and no history of exposure to that metal. The faradic excitability of the extensor communis of the right arm was lessened and A S Z > K S Z. The hand felt numbed. There had been no pain in the arm. There was no sign of lesion in the other arm, or in the lower extremities. The knee-jerks were present and equal. Under treatment, chiefly by abstinence and with slight application of electric currents, he quite recovered in six or seven weeks.

In another example the lesion was confined to the brachial plexus of one side.

A gentleman, aged twenty-two, came to me from a medical man in the country. His right arm hung helpless. It was exquisitely tender to the touch, full of pain, and presented a sodden appearance. Pains had begun in the arm some weeks previously. For some two or three years, I was informed, his habits had been most intemperate, and he had been on the verge of *delirium tremens* when the attack of brachial neuritis began. At first its occurrence appeared to check the development of the symptoms of delirium, but when he returned home he was in a half maniacal condition, which prevented an exact examination of the arm being made. He had been then treated with salicylates, bromides, iodides, arsenic, and quinine. Under antipyrin, grains 25, and extract of Indian hemp, grain ¼, three times a day, he soon began to have less pain and tenderness. In a fortnight he looked very much better, and was free from pain. I heard later that he had quite recovered.

A female patient was brought to me on account of loss of power in the right hand and greatly impaired vision. I found the right grasp diminished in power. The two middle fingers were especially weak, and tended to drop. There was no cutaneous anæsthesia. She had suffered from what she called "rheumatism"—sharp shooting pains in the feet and across the instep for years, but had had no pain in the arms. In the course of the last six years she had on three occasions an epileptic fit. The difficulty of vision was peculiar. At first it strongly suggested hemiopia. Looking at the word "holding," she could read "hold" only. After a pause and apparently readjusting her gaze, she saw the remainder of the word. Facing me, she could see my right eye clearly, my left but very indistinctly. Yet, on holding up my fingers, and testing the field of vision, I could discern no impairment of the extent to which she could see to her right and left. It appeared, therefore, that she had a scotoma just to the right of the center of the visual field. Her tongue appeared slightly inclined to her right. This last symptom, coupled with the suggestion of hemiopia, paresis of the right arm, and the history of fits, might easily lead to a diagnosis of intracranial disease. But close investigation did not confirm this.

The extensor communis muscle of the right arm showed distinct lowering of excitability to both faradism and galvanism, but especially to the latter. This could not result from an intracranial lesion. It pointed to an affection of the "spinal" nervous system, and was most probably due to peripheral neuritis. (The word "spinal" connotes, of course, the spinal nerves as well as the cord). There was a history of alcoholism. I was disposed to refer the scotoma to periaxial neuritis of the optic nerve. The patient recovered completely in a few weeks.

I saw quite recently in consultation a lady, aged sixty-four, who a fortnight previously had entirely lost the use of the right arm. Investigation of the cause of this monoplegia excluded a traumatic origin. The tendon reflexes in the other arm and in the legs were good. In the right arm they were absent. There was total inability to move any muscle of the right upper extremity, including the shoulder, together with anæsthesia of the hand, which decreased shortly above the wrist. Pain of excruciating character, especially bad at night, was described as affecting the right arm. It was as though the "limb were being torn out of its socket on a rack." I had not an opportunity of testing the faradic excitability of the muscles, which were very flaccid, but the other symptoms are sufficient to show that the lesion was probably a neuritis of the brachial plexus. The patient was described as not having been sober for a year past.

These examples, I have thought, would prove interesting and valuable, as tending to show what has

not yet, so far as I know, been advanced respecting the influence of alcohol, that its effects may appear, not only in the more common form of a generalized paralysis of the extremeties, but in lesion of a peculiarly localized character. If I am right in the view that these are examples of localised neuritis due to alcohol, it is evident that we shall have in future to bear this possibility in mind, when we meet with neuritis of single nerves or plexuses, of the cause of which we do not find a ready explanation.

Let us turn now to peripheral neuritis arising from other causes than the influence of alcohol. A week or two after I had published a work on "Paralysis from Peripheral Neuritis," the following case came under my observation at the hospital. It is one of multiple neuritis, occurring in a patient affected with diabetes melitus :

J. K., aged fifty-five, carpenter, applied to the National Hospital for the Paralyzed and the Epileptic, on June 30th, 1886, suffering from loss of power in the lower extremities, which he ascribed to working in the wet. He had been quite well until the previous September, when, after working daily for several weeks out of doors in the cold and wet, he began to get pain and tenderness in the front of the right thigh, which extended presently down the leg to the foot. The pain was very severe, and there was so much weakness that his knee often gave way and let him down. A month after the right the left leg was similarly attacked, and in three months from the first symptoms he could not walk at all. About this time he noticed also numbness and "pins and needles" in both legs, especially in the soles of the feet, and the pains were severe and continuous. The symptoms continued till the end of February, when the pains became less severe, and he became able to walk upon crutches. The improvement in his lower limbs continued, but towards the end of May he began to have a little tingling and slight numbness in the tips of his fingers. At no time was there any difficulty with his bladder, but soon after the commencement of his illness he was troubled with great thirst and noticed that he passed much urine, and, moreover, wasted in flesh a great deal.

On examination, the legs were found thin ; they could be flexed readily upon the thighs, but extension was imperfectly performed. There was no power of dorsal-flexing the feet upon the legs. There was tenderness on pressure in the soles of both feet, and he complained of tingling and numbness from the feet up to the knees—more in the feet, ankles, and front of the legs than in the calves. There was much loss of cutaneous sensibility in the feet and lower part of the legs. The knee-jerks were absent. There was no response to the strongest induced currents in the anterior tibial group of muscles, and this painful application could be borne without inconvenience in that situation, whilst lower down it was only felt as pressure. It was remarkable, I may note by the way, that some immediate return of voluntary power in dorsal-flexing the feet followed this application, although the electric current itself caused no muscular contraction. Examinations of the urine showed that it contained a large quantity of sugar.

The man was admitted as an in-patient a fortnight afterwards. Examination then showed the plantar reflex fair on the left, but hardly to be obtained on the right sole ; the gluteal fair on the left, not well marked on the right ; the cremasteric also better on the left than the right side. The abdominal and epigastric reflexes were present on each side. There was a ready and normal response to induced currents in the muscles of the hands and arms, but still no reaction in the anterior tibial group ; the calf muscles responded, though not perfectly, and the muscles of the thighs also responded, to the induced current. A strong galvanic current was required to cause contractions in the anterior tibial muscles, but the response took place on the right side to twenty-eight cells with the positive-pole closure, as against thirty-four cells with the negative-pole closure. On the left side, too, the positive-pole closure contraction was more marked than the negative. On the other hand, in the right gastrocnemius only twenty-two cells were required with the negative pole, as against thirty-two with the positive, A fortnight later a very strong faradic current produced contractions in the anterior tibial group, but a much weaker current was sufficient to act upon the peroneal muscles.

When he left the hospital, at the end of August, K S Z > A S Z in the anterior tibial group. There was still great loss of cutaneous sensibility in front of the legs.

Examination of the urine showed that it was passed in large quantities and of high specific gravity, as the following figures will indicate :

July 25th,	74	ounces	in the	24	hours,	specific gravity 1045,
" 26th,	79	"	"	"	"	" 1043,
" 27th,	94	"	"	"	"	" 1042,
" 28th,	84	"	"	"	"	" 1042.

The urine contained sugar in abundance.

The patient was shown to the Harveian Society in November, 1886. After remaining as an out-patient during the winter and spring, he was again admitted into hospital in June, 1887, still complaining of great loss of power in both lower limbs, the movements of which were feeble. There was drooping of the toes of the left foot. Both legs were slightly wasted. The knee jerks and plantar reflexes were absent. There was continuous pain in both legs and feet, and some but less numbness than formerly. Sensation to touch was diminished below the knees. In the same region there was slight tenderness on pressure.

On the outer side of the right foot, just below the external malleolus, was a deep ulcer, the skin around it and on the outer side of the foot generally being much congested. This had begun as a small swelling, which had gradually increased in size, burst, and discharged a small amount of pus.

On the sole of the left foot, just below the metatarso-phalangeal joint of the great toe, was a cicatrix due to a similar condition, which had arisen in connection with a corn in that situation, in the February preceding.

Tactile sensation was diminished in both hands, and the patient complained of slight pain in both hands and the left forearm. There was pain in all the fingers of the left hand, and in the little and ring finger of the right hand. There was loss of power in both hands, especially in the left, and the power of flexing the elbow was much feebler on the left than on the right side. There was wasting of the thenar and hypothenar eminences of both hands, and of the interrossei (especially of the first) in both hands ; also slight wasting of the left forearm.

From the middle to the end of July the diet consisted in toast, green vegetables, meat, eggs ; no potatoes, sweets, beer, rice, or other starchy food. The quantity of urine averaged fifty-seven ounces per diem, and by the fermentation process the amount of sugar was estimated at an average of twenty-five grains per ounce of urine.

From the end of July to the middle of August soft bread was substituted for toast, with the result that the urine averaged eighty-three ounces per diem, with thirty-five grains of sugar per ounce of urine.

From the middle of August until the middle of October gluten bread replaced the soft bread previously taken. The quantity of urine fell to an average of fifty-four ounces per diem, with only sixteen grains of sugar per ounce of urine. *Pari passu* with this decrease of glycosuria, the patient gained weight, the ulcer healed, and when he left the hospital, on November 3d, his condition generally was described as much improved. I have since lost sight of him.

When I first saw this man in the out-patient room, I recognized his case as one of a class to which (in order to distinguish them from those resulting from disease of the cord) I have suggested the name of neuritic paraplegia. The basis or ultimate cause of the neuritis did not at once appear evident, as there was no alcoholic history. It was in an endeavor to discover this, and influenced by the man's description of thirst and wasting, that I examined the urine for sugar. Just at that time the occasional dependence of peripheral neuritis upon diabetes had been announced abroad, and I was much interested in meeting with a case in point. The occurrence of perforating ulcers in this case is very interesting. From this, together with the absence of knee-jerks, and the pains, the case might readily, but for the discovery of the sugar and the existence of muscular atrophy, have been set down at first sight to one of tabes dorsalis, with which it had much in common.

In another case, to which I need only very briefly refer, symptoms of pains and weakness of the extremities, with absence of knee-jerks, had been ascribed to tabes. In that instance I discovered a large quantity of sugar, and under a partially restricted dietary there was remarkable improvement in the symptoms and the knee-jerks returned. The symptoms in this case had never attained the severity observed in the preceding one. There had been no considerable loss of power, and the muscles showed no atrophy. In another, seen recently in consultation, a diabetic patient suffered from excruciating pain in the lower extremities with loss of knee-jerks. In the following example the paralysis and atrophy were strongly pronounced, and much more localized than in the first example.

A gentleman, aged sixty, was sent to me in October, 1887, with the left arm hanging helpless and its muscles wasted. He told me that he was suffering from diabetes and that he had much gout. Sugar had been discovered six years, and he passed about fifteen grains to an ounce. Albumen had been observed eighteen months, and it measured about a twentieth. The sun of a gouty father, he had always drunk beer and port wine, and began to show gout at forty years of age. His appearance was that of a man who had lived freely. His heart-sounds were feeble, and he had an aortic systolic *bruit*. He passed in the twenty-four hours about six pints of urine, usually of a specific gravity of one thousand and twenty-five. This was on a partially restricted dietary. On ordinary diet it would rise to one thousand and forty or more. He was taking six ounces of whiskey daily, besides some wine. His weight, which had been formerly eighteen stones ten pounds, was then about fourteen stones.

Examination showed wasting of all the muscles of the left shoulder and arm, except the flexors of the wrist and fingers. In these only reaction to the induced current persisted, although it was diminished. In the wasted muscles there was none. There was much œdema of the hand, and the sensibility of the skin of the arm was much diminished. Only the left shoulder and arm appeared to be affected. The atrophy had been preceded by great gnawing pain about the shoulder, with shooting down the arm, which had begun, according to the patient's account, about a month previously. There were no knee-jerks.

When I saw this patient five months later, he could lift the shoulder and elbow, which he had not been able to do when he was first examined, but electrically there was no improvement. There was no reaction to the strongest induced current in the muscles of the shoulder, arm, and extensor side of the forearm; the flexors of the wrist and fingers required also a strong current. The skin of the shoulder of the right side was but little sensitive to induced currents, and he had been complaining of pain in that situation.

In June, 1889, I again saw this patient in consultation at his own house. He was then suffering from congestion of the base of the left lung. Both his arms were now very incapable.

I recently saw a female whose gait was shambling, and who could scarcely use her hands. There was a history of pains in the feet, gradually extending up the legs, of a sharp character, from which she had suffered for three years. She had no knee-jerks. Pupils reacted to light. There was anæsthesia below the knees. She could dorsal-flex the feet, but the legs were very weak. Her memory was good. There was no appearance or history of alcoholism. I suggested to her medical attendant to examine the urine for sugar. He found it of specific gravity one thousand and forty-two, and highly charged with sugar.

It appears from a case recently published by Dr. Althaus that the neuritis in diabetes may be limited to a single nerve.—*British Med. Journal.*

TUBERCULOUS CATTLE.—The following official statistics, relating to the public slaughter-house of Augsburg, may be interesting: During 1889, of 23,592 calves slaughtered, only one (an animal three weeks old) was found to be tuberculous. Of 13,679 head of older cattle, 612, or 4.4 per cent., were tuberculous. Of 8,537 oxen, 167, or 1.94 per cent. were tuberculous; while of 5,008 cows, 445, or 8.88 per cent., were affected with that disease. In four cases, or almost one per cent. of the cows, the udder was the seat of tuberculosis. In 67 of the 612 cases, in which disease was discovered, the flesh was declared unfit for food on account of generalized tuberculosis, and destroyed.

DR. JOHN RIDLON, clinical teacher at the Vanderbilt *clinique* in connection with the College of Physicians and Surgeons, New York, lately gave a lecture and demonstration on the subject of Potts's spinal caries, at the Royal Southern Hospital, Liverpool. The apparatus he employs for fixing the spine is a modification of Taylor's, differing from it in this, that the pressure is made over the transverse processes of the vertebræ, and not, as in Taylor's apparatus, over the ribs. The basis of support is formed by a steel band, passing behind the sacrum and between the iliac crests and the great trochanter, resting on the latter. From this two upright steel bands pass, one on each side of the line of vertebral spines, and terminate in a strap that passes round the shoulder and axilla. Above and below the point of deformity there is a transverse bar attached, having at either end a strap which passes forward and is secured to an

apron which covers the front of the patient. On each side of the deformity pressure is made along the line of transverse processes by cork pads attached to the upright bars. The advantages claimed for this apparatus are that the deformity is controlled to the greatest possible extent by the pressure being made on the transverse processes, and that there is no possibility of the angle slipping to one side. When the disease is in the upper dorsal region, a support for the chin is added ; and a frontal band is employed, when it is in the cervical region. With regard to diagnosis, Dr. Ridlon regards rigidity of the spine as the most constant and unmistakable symptom of Pott's disease, being present from its earliest onset, and only disappearing when the cure is complete. Local pain and tenderness at the point of disease he regards as never occurring in uncomplicated caries of the bodies of the vertebræ, and if found in any case suggests that the condition is not Pott's disease at all. The lecture was listened to with much interest by several practitioners in the neighborhood, and a hearty vote of thanks was accorded to Dr. Ridlon.

On the Strumous Diseases of Childhood and Their Relation to Tubercle.[1]—During a long experience as physician to the first hospital for diseases of children established in Ireland, with which I have been connected since its foundation, in 1872, the increasing prevalence of the strumous and tubercular diseases of childhood have been constantly brought under my clinical observation. The intimate connection and relation between these conditions was pointed out nearly a quarter of a century ago in my work on "Change of Climate," and was discussed in a paper of mine in the Transactions of the International Medical Congress of 1871, as well as last year in my article on *Puberty*, in Dr. Keating's recently-published American "Cyclopædia of Diseases of Children." I refer to these dates merely as evidence that the views embodied in the following brief recapitulation were not hastily formed nor without some experience of the subject referred to. The increasing proportion of strumous and tubercular affections which have been observed of late years in my wards in the Children's Hospital, is probably largely ascribable to the faulty dietetic and hygienic management of early childhood, and to the general substitution of artificial, and in many instances very unsuitable, preserved or tinned preparations, for that natural or fresh milk which, in my opinion, is essential for the healthy nutrition of children. As I formerly pointed out, and the observation is now more applicable than was the case ten years ago, the acute forms of tuberculosis common during childhood resemble the infective diseases in their origin from a specific germ, whether generated in the body or introduced from without. The latter is probably the case in the tubercular diseases prevalent amongst the children of the poor, in whose dietary various forms of preserved milk foods now enter largely, as it seems difficult to conceive any certain guarantee that the cows furnishing the supply may not, in some cases, suffer from *perlsucht*, this disease being very prevalent and not materially affecting the quantity of milk. More recently Prof. Bollinger has shown that milk may prove infectious whether taken from cows suffering from general or local tuberculosis. In his experiments only a few drops of undiluted milk from a tuberculous cow proved sufficient to produce miliary tuberculosis in animals. Be the pathogenesis of tuberculosis what it may, however, can, I think, be no question as to the fact that it is most frequently developed in patients who bear in their general constitutional condition, and more especially in their glandular system, the obvious imprint of the strumous diathesis. Nor is it to be wondered at that in children thus constitutionally enfeebled the struggle for existence between the invading specific microorganisms and the blood corpuscles, or leucocytes, should almost invariably so speedily terminate in the fatal victory of the prolific bacilli of tubercle.

—Thomas More Madden.

Medical News and Miscellany.

Dr. Sharp sailed for Boston on Tuesday.

Prof. J. M. Anders has been inspecting Sea Isle.

Prof. Duhring has honored Atlantic City with a brief visit.

Women are admitted to the classes of all Italian universities.

The reports from Spain show that the cholera is raging there.

"La Grippe" is said to be responsible for a large number of suicides.

Philadelphia has 1095 arc lights, and 892 miles of underground electric wires.

Dr. G. Howard Beck has been appointed Police Surgeon for the Fifteenth Ward.

The Seaside Home at Cape May Point has begun its beneficent work for the summer.

A Detroit electric-light company insures the lives of its employés for five thousand dollars each.

The dragon-flies are said to have completely cleared Light-house Point of mosquitoes. A pointer for Cape May Point.

Sweet milk was so scarce during the late hot spell in New York that milkmen got double the price usually charged.

"Dr." Bradley, the diploma vender, has been indicted. He has destroyed his plates and surrendered diplomas and seals.

Dr. George I. McLeod, of Thirty-ninth and Chestnut streets, sailed on Wednesday, July 9th, by the Bothnia, for Europe.

A rabid sea-lion took possession of a Santa Fé train and held it until death. The carcass was taken to Armour's packing house.

Dr. Iliff, of Philadelphia, showed his keen appreciation of the comforts of life by taking up his abode at the Mansion, Atlantic City.

Dr. Judson Daland spent last Saturday and Sunday at Cape May. The doctor is looking well and hearty ; he is quite fond of swimming.

The Lippincott homestead, at Palmyra, N. J., has been opened as a sanitarium for sick children, under the supervision of Dr. Francis Janney.

MR. TABBOT, of Boston, has opened a summer camp for boys, on the borders of Lake Asquam. Lucky boys! Wish we were one of you!

THOSE old friends, the cholera scare and the man who "points with pride" in the political platforms, have commenced their summer campaigns.

DRS. D. C. POSEY AND ROBINSON, of the Presbyterian Hospital, have just returned from Elberon Springs, where they had a pleasant holiday.

THE ptomaine produced by the bacillus of mice septicæmia, is called methylquanidine. One-thirty-second of a grain is sufficient to kill a rabbit.

THE account of the remarkable birth of quadruplets in the *Dietetic Gazette* seems to have been copied by every small medical journal in the United States.

DRS. ALLIS and Posey are said by the *Times* to have performed the rare and difficult operation of herniotomy at the Presbyterian Hospital last Saturday.

DIET during summer complaint of infants should be determined entirely by the condition of the bowels, and not by theoretical ideas as to Nature's food.

BROOKLYN'S death rate is on the increase. There were 552 deaths during the week ending July 5, representing an annual death rate of over 33 in every 1,000.

DR. E. M. WILLIARD, one of the visiting staff of the Presbyterian Hospital, left for Europe on Wednesday, July 9th, and will be away during the summer months.

A PIN was lately removed from the ear of a woman at the University Hospital. She had used it to stop itching, when it slipped into her ear and penetrated the drum-head.

THE summer home for the deaconesses of the German Hospital at Cape May Point is occupied by the Sisters and Dr. Marie L. Baŭer. The mosquitoes take kindly to Teutonic blood.

THE State Factory Inspectors, in four and a half months, made one thousand one hundred and twenty-seven inspections and only found forty-two children under twelve years of age.

A MICHIGAN druggist sold alcohol to a fifteen-year-old boy, who, with his little brother, got drunk on it, and both were killed on the railroad. The parents are suing the druggist for damages.

THE physicians of New Orleans, who started a training-school for nurses, having failed, the ladies took it up, and have carried it through the first year with a fair prospect of success.

THERE is a Flour, Fruit and Ice Mission which meets weekly at Horticultural Hall for the purpose of distributing contributions of the above to the different hospitals of Philadelphia.

SEVERAL children were poisoned in Bridgeport, Pa., last week, by eating blackberries from bushes on which Paris green had been sprinkled, to poison insects that were eating the leaves.

POSTMASTER-GENERAL WANAMAKER, last week, attended the exercises at a sea-side home for the sick recently established at Ocean City by the Bethany Sunday-school, of Philadelphia, of which he is superintendent.

THE Children's Country Week Association, last week, sent three hundred and twenty-six children to points along the main line of the Pennsylvania Railroad and Baltimore Central Division.

HENRY M. STANLEY will lecture in the Metropolitan Opera House, New York, for the benefit of the Fresh Air and Benevolent Home of Summit, N. J., shortly after his arrival in this country.

MRS. ISABELLA BIRD BISHOP, the famous traveler, has obtained from the Maharajah of Kashmir the grant of a piece of land on which to build a hospital of sixty beds and a dispensary for women.

A CAT which had been recently bitten by a supposed mad dog, in Beverly, Massachusetts, attacked and bit two little children of J. C. Edwards, and tore the hands of Charles Grenough, who killed the animal. The wounds were cauterized.

THE next meeting of the Fifth District Branch of the New York State Medical Association will be the eighth special meeting, to be held in Kingston, Ulster county, New York, on Tuesday, July 22, 1890. A large attendance is desired.

SOME months ago we mentioned the advantages of working women donning masculine garments. A Berks county farmer's wife arrayed herself in her husband's clothes and mounted the reaper, but the harvesters refused to work with her.

THE *Chicago Medical Times* states that the Bennett (Eclectic) Medical College parted with their late Dean because he sold a diploma of the college for $100 to a man who had only attended one course of lectures, applied for graduation and was refused.

ACTING on the report of its experts in regard to the steam heating nuisance, the Board of Health issued orders to the New York Steam Heating Company to shut off its steam and discontinue the use of its mains at four different points in the city.

THE German joke is calculated to give one a pain in the stomach. The *Fliegende Blatter* says a physician is noted for his generosity because he attends people without asking a fee; he settles with the heirs. The key to the combination will be over by the next steamer.

THE *Medical Press* quotes a medico-legal case which the railway doctor pronounced an attempt at imposition; while two distinguished surgeons held that the spinal injury was so serious that it would require from one to two years of the most skilful treatment to cure.

THE party of ladies and gentlemen who tramped to Atlantic City took a pleasant and profitable method of spending their vacation. Pedestrian tours open up a succession of pleasant surprises to those who have only seen a section by glimpses from a flying express train.

MR. THEODORE WARNE has left THE TIMES AND REGISTER, to accept a position at Peter Wright & Sons, and his place, as manager of the subscription department, has been filled by Mr. George Wharton McMullin, who retires from the advertising department, where his place has been filled by the energetic Dr. Giles. Mr. McMullin has been connected with the journal ever since the first issue of the old *Medical Register*, with the exception of a few months during the summer of 1887, when he returned to his labors as the successor of Dr. William C. Wile.

DR. M. J. ROSEMAN, of the resident staff of the Almshouse, who received a commission as surgeon in the United States Marine Corps, and Dr. Frank Keefer, who passed at the head of forty-eight applicants as surgeon in the United States Army, are waiting to be ordered to report for duty.

A MEDICAL BISHOP.—The Right Reverend Henry Callaway, Bishop of St. John's, Caffraria, South Africa, who died March 26, was a regularly qualified practitioner of medicine and surgery, his M.D. degree having been granted by the King's College, Aberdeen, in 1853. He was in his seventy-third year at the time of his decease.

DR. LANPHEAR may see the truth of the old adage that a slander goes much farther than its denial, in the re-publication of its circulation item by the *Weekly Medical Review*. Dr. Lanphear published a statement concerning THE TIMES AND REGISTER which was untrue. He should at least give equal prominence to our denial.

THE St. Louis College of Physicians and Surgeons is erecting a new college building; to be completed by October 10. It is a handsome structure, 75x119, with three large lecture-rooms and all other needed appurtenances.

The Beaumont Medical College is also being rapidly pushed to completion.

DURING June, 38 new cases were admitted to the Germantown Hospital; 30 cases were discharged, and 1 died. Remaining in the Hospital June 30, 32. In the general dispensary 294 cases were treated. In the eye department there were 107 cases; in the nose, 16; ear, 21; and throat, 24 cases. During the month there were 19 ambulance calls.

AT the regular meeting of the Managers of the Pennsylvania Society for the Prevention of Cruelty to Animals, held on Tuesday, of last week, the operations of the month showed that 920 cases of abuse and cruelty had been attended to, resulting in 23 arrests, 395 sore and lame horses and mules were turned out of harness, and 263 cases remedied without prosecution.

AMONG the mountain resorts which are becoming quite popular this summer, are the Hotel Kaaterskill, Paxinosa Inn, Lake Hopatcong, and Swiftwater; the latter in Monroe county. Wernersville has several good hotels in its vicinity. No one who has not visited it would imagine that such beautiful mountain scenery is to be found within two or three hours' ride from Philadelphia.

IN his report upon the Convention for the revision of the U. S. Pharmacopœia of 1890, Dr. Benjamin graphically demonstrates the business capacity of the preceding committees. The work was given out to be published by a New York house, which realized profits of somewhere between $20,000 and $54,000, while the distinguished but stupid men who did the work received nothing.

"A SECOND SARAH."—A woman living in the mountains near Fort Smith, Ark., named Sarah Gates, aged seventy-one years, proved herself almost a second Sarah by giving birth to a well-formed and healthy male child. Two years ago, Mrs. Gates, then a widow, married William Gates, a young hired hand on her farm. The case is exciting a good deal of interest among physicians.—*Med. World.*

THE TIMES AND REGISTER stands out, solitary and alone, as the one and only medical journal that said a good word for Billing's census circular. If this doesn't make us solid for the next $30,000 investigating committee, then gratitude has ceased to inhabit the human heart.

THE remark that rabies flourishes in proportion to the development of Pasteur institutes, reminds us of a similiar objection made to vaccination. It was said that the number of vaccinations reported by the Board of Health was greatest during the times when small-pox was prevalent.

MINNEAPOLIS is wrongly supposed to be a wide-awake place; but an esteemed contemporary tells of one of her citizens who slept for three weeks at a stretch; only waking for food. As the case seems to have excited no comment in the Minneapolis journals, we suppose such somnolence is the usual state of that city. St. Paul papers please copy.

THE Misses Stewart, of Cincinnati, three Scotch ladies, have for two years kept a temperance restaurant in the Chamber of Commerce building. It was predicted that they could never make it pay if they refused to furnish beer; but the plucky Scotchwomen stuck to their principles, and their cooking is so good that they clear from $8,000 to $10,000 annually, besides paying a rent of $3,000 a year for their handsome premises.

The Pulte Quarterly takes a shy at the question of the eligibility of homœopathists for the Army and Navy Medical Corps, and quotes the army regulations to the effect that candidates must be graduates of a regular medical college. This is correct as far as concerns the army; but in the navy there is no rule requiring the applicant to be a graduate of any college. In fact, we know of at least one who entered the service before he graduated.

THE *St. Louis Medical and Surgical Journal* devotes an editorial to the alleged discovery of a fresh-water sponge as the microbic cause of eczema rubrum. The editor states that Dr. Wilkins sent him a slide upon which was a specimen obtained from the patient by his own hands; but which the editor declares contained, not sponge-spicules, but human spermatozoa. This is, to say the least, calculated to throw some doubt upon Dr. Wilkins' claims.

THE glorious Fourth supplied the Boston City Hospital with twenty-one injuries from explosions; the giant cracker figuring largely in the etiology. The *Boston Medical and Surgical Journal* says that a feature of these injuries is the splitting open of the base of the thumb, and production of a compound dislocation at the joint of the first metacarpal and the trapezium, so that the thumb and its metacarpal are connected with the hand only by the soft parts.

ONE hundred and fifty men, women and children, at a church picnic at Solon, near Iowa City, were prostrated last Sunday with serious symptoms of poisoning. In a few moments the people had fallen from the tables upon the ground writhing in pain. Physicians were summoned and administered remedies, in a few hours the patients recovered, no case being fatal. The use of water from a well long abandoned is given as the cause of the sickness.

THERE have been several cases of small-pox on the ship "Saratoga," landing at Mauritius, and some uneasiness is expressed. The local health board,

owing to contagious disease on the "Saratoga," and the possibility of the introduction of cholera from Europe, will establish a local quarantine station in Longue Isle Bay, where all suspected incoming ships will be thoroughly fumigated, and detained until the health officer is satisfied no trace of disease exists.

T. DE WITT TALMAGE says that no one can do with less than six or seven hours sleep per day; and warns his audience against the fairy tales of great men who slept but three or four hours a night. Americans need more sleep than they get, and the lack of it is one of the elements which render insanity and nervous diseases frequent. No man or woman ever yet kept healthy in body and mind for a number of years with less than seven hours sleep.

THE following report is made of the work at the Woman's Hospital for June: Patients treated in the house, 116; discharged, 47; new patients treated in clinic, 596; gynæcological, 177; medical, 113; surgical, 70; eye, 63; ear, throat and nose, 74; dental, 14; electrical, 85; visits to clinic, 2,615; new out-patients, 69; visits to out-patients, 310; operations in hospital, 55; births in hospital, 12; in out practice, 5; prescriptions compounded, 2,867; nurses in service at hospital, 44.

DURING May, New Orleans reported 600 deaths. The principal causes were:

Consumption	63
Cholera infantum	49
Diarrhœa	39
Pneumonia	32
Senile debility	26
Cancer	20
Bright's disease	16
Meningitis	13
Infantile debility	12
Bronchitis	11

HERE'S RICHNESS.—Adametz has isolated nineteen varieties of microbes in a single variety of cheese in the fresh condition. In each gramme he counted from 90,000 to 140,000 bacteria, which in seventy days had multiplied to 800,000. In the soft varieties the number is still greater: 1,200,000 in a gramme of cheese thirty-four days old, and 2,000,000 in another forty-five days old. These figures refer to the interior; in the rind, three to five millions of organisms were counted per gramme.—*Lyon Medical.*

THE Alvarenga prize of the College of Physicians of Philadelphia, consisting of $180—one year's income from the amount of the bequest of the late Dr. Pedro Francisco de Costa Alvarenga, of Lisbon, Portugal—has been awarded to Dr. R. W. Phillip, of the Victoria Dispensary, Edinburgh, for consumption and disease of the chest, for his essay on pulmonary tuberculosis. This is the first year that the prize has been awarded, and each year hereafter it will be awarded for the best memoir or unpublished work in any branch of medicine.

IN the monthly report of the Medical Superintendent of the Cherokee (Indian Territory) High Schools that on the female seminary (the pride of the Cherokee Nation) closes with this remark: "We have beautiful, roomy grounds at the seminary, and my advice to the young women would be to play base-ball, run and swing, get more of the good fresh air and sunshine, so as to develop the lungs. When a chief of the Cherokees was asked why the Cherokees are so much in advance of the other tribes, he replied: 'Because we have taken care to educate the women as well as the men.'"

THE Seventeenth Annual Session of the Mississippi Valley Medical Association will be held at Louisville, Kentucky, October 8, 9, and 10, 1890. The medical profession is respectfully invited to attend. The meeting promises to be of great social and scientific interest, as the profession of Louisville are doing their utmost to make it a success. Ladies accompanying physicians will be made especially welcome. Gentlemen wishing to read papers will please send titles as soon as possible to the Secretary, Dr. E. S. McKee, 57 W. Seventh street, Cincinnati. The American Rhinological Association will also meet in Louisville, October 6, 7, and 8, 1890.

THE Eighteenth Annual Meeting of the American Public Health Association will be held at Charleston, S. C., December 16, 17, 18, 19, 1890.

The Executive Committee have selected the following topics for consideration at said meeting:

1. Sanitary Construction in House Architecture; (*a*) Heating, (*b*) Lighting, (*c*) Draining, (*d*) Ventilation. 2. Sewage Disposal. 3. Maritime Sanitation at Ports of Arrival. 4. The Prevention and Restriction of Tuberculosis. 5. Isolation Hospitals for Infectious and Contagious Diseases. 6. Establishments in Favorable Climates for Persons having Tuberculous Predispositions; (*a*) Schools for Children and Adolescents, (*b*) Sanatoria, (*c*) Permanent Residence. 7. Miscellaneous Sanitary and Hygienic Subjects.

PATENTS issued during the past week. Reported by Charles G. Gooch, counsellor in patent cases.

Obtaining acetic acid and methyl alcohol	F. C. Alkier	Wieselburg, on the Erlauf, Germany.
Rosinduline sulpho acid	C. Schraube	Ludwigshafen, o. t. Rhine, Germany.
Remedial cosmetic	C. J Wilkins	Denver, Colo.
Fountain syringe	C. A. Tatum	New York, N. Y.
Making thio-oxydiphenylamine	M. Lange	Amersfoort, Netherlands.

TRADE MARKS.

Blood purifiers, tonics, and like remedies	W. S. Burnham	Cleveland, O.
Medicinal bark known as Cascara Sagrada	S. L. Jones & Co.	San Francisco, Cal.
Liniments capable of use externally and internally	W. M. Bagley & R. W. Tilford	Greenville, Miss.
Various medicinal remedies as specified	F. Eberlein	Chicago, Ill.
Natural mineral water	Coronado Water Co.	Coronado, Cal.
Remedy for diseases of the liver, kidneys, and stomach.	J. W. Jones	Americus, Ga.
Remedy for hog and chicken cholera	G. Riley	Fayetteville, Ark.
Suppositories for curing female diseases and piles	D M. Coonley	South Bend, Ind.
Bronchial syrup	G. S. Hull	Lowell, Mass.

LABEL.

"Emley's Liniment"	C. A. Emley	Wrightstown, N. J.

GERMAN MEDICAL DIPLOMAS.—In the numerous small free faculties of Germany, the medical students pass their examinations in the following manner:

"Do you smoke?" asks the examiner.

"Yes, sir," answers the student. "Will you have a cigar?" (*Hands the professor a pfenning cabbage leaf cigar.*)

"Tell me," says the professor (*slowly lighting his weed*), "what are a physician's principal duties?"

"To collect his fees, increase his practice, and exhibit his diploma from the time-honored "University of Guzzleburg," replies the student.

"Where shall you practice?" demands the professor, "and what are your duties towards me?"

"I shall go to America among the ignorant natives and make a golden harvest. And my duty towards you, Herr Professor, is to invite you to dinner for the rest of the semester," answers the student.

The professor smiles and says: "You are right. Let us go to a restaurant opposite and I will sign your diploma. The diplomas of the time-honored 'University of Guzzleburg,' are admired and respected in America. I have a cousin who is a doctor in Chicago. Let me tell you how the Indians chased him on Prairie avenue. He was wounded twice by their arrows and captured, but was released by his pursuers when they found on his person the time-honored diploma of the 'University of Guzzleburg.' Ah! here's the restaurant, and I will make out your diploma from the time-honored 'University of Guzzleburg.' "—*Lancet Clinic.*

WHILE cross-examining Dr. Warren, a New York counsel declared that doctors ought to be able to give an opinion of a disease without making mistakes.

"They make fewer mistakes than lawyers," responded the physician.

"That's not so," said the counselor; "but doctors' mistakes are buried six feet under ground, and lawyers' are not."

"No," replied Warren, "but they are sometimes hung as many feet above ground."

—*Montreal Legal News.*

WEEKLY REPORT OF INTERMENTS.—Deaths and Interments in the City of Philadelphia, from the 5th of July to the 12th of July, 1890:

CAUSES OF DEATH.	Adults.	Minors.	CAUSE OF DEATH.	Adults.	Minors.

TO CONTRIBUTORS AND CORRESPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from June 28, 1890, to July 10, 1890.

By direction of the Secretary of War, the following-named Assistant-Surgeons (recently appointed) will report in person for duty to the commanding officer of the various posts designated opposite their respective names:

First Lieutenant Frank R. Keefer, Fort Leavenworth, Kan.
First Lieutenant Thos. M. Raymond, Fort Sherman, Idaho.
First Lieutenant Henry D. Snyder, Fort Reno, Indian Ty.
First Lieutenant Allen M. Smith, Fort Snelling, Minnesota.
First Lieutenant Ashton B. Heyl, Fort Nebraska, Nebraska.
First Lieutenant Joseph T. Clarke, Fort Riley, Kansas.

Par. 6, S. O. 151, A. G. O., June 28, 1890, Washington, D.C.

CORBUSIER, WM. H., Captain and Assistant-Surgeon, is relieved from duty at Fort Lewis, Colorado, and will report in person to the commanding officer, Fort Wayne, Michigan, for duty. S. O. 151, par. 7, A. G. O., June 28, 1890, Washington, D. C.

BALL, ROBERT R., First Lieutenant and Assistant-Surgeon, is relieved from duty at Fort Riley, Kansas, and will report in person to the commanding officer, Fort Spokane, Washington, for duty. S. O. 151, par 7, A. G. O., June 28, 1890, Washington, D. C.

By direction of the Acting Secretary of War, leave of absence for four months is granted Major James P. Kimball, Surgeon, to take effect when an officer of the Medical Department is assigned by his department commander to relieve him. Par. 6, S. O. 152, A. G. O., July 1, 1890, Washington, D. C.

ROBINSON, SAMUEL Q., Captain and Assistant-Surgeon, is relieved from temporary duty at the U. S. Military Academy, West Point, New York, to take effect upon the arrival there of Captain W. Fitzhugh Carter, Assistant-Surgeon, and will report in person to the commanding officer, Fort Du Chesne, Utah Territory, for duty, relieving Captain Curtis E. Price, Assistant-Surgeon. Captain Price, on being relieved by Captain Robinson, will proceed to Fort Wadsworth, New York Harbor, and report in person to the commanding officer of that post for duty, relieving Captain Robert B. Benham, Assistant-Surgeon. Captain Benham, on being thus relieved from temporary duty at Fort Wadsworth, will report in person, without delay, to the commanding officer, Fort Hamilton, New York Harbor, for duty. Par. 12, S. O. 153, A. G. O., July 2, 1890, Washington. D. C.

GARDINER, JOHN DE B. W., Captain and Assistant-Surgeon, having been found incapacitated for active service by an Army Retiring Board, and having complied with paragraph 12, S. O. 135, June 10, 1890, from this office, is, by direction of the Acting Secretary of War, granted leave of absence until further orders, on account of disability. Par. 3, S. O. 153, A. G. O., July 2, 1890, Washington, D. C.

By direction of the Secretary of War, the leave of absence on surgeon's certificate granted Captain Marcus E. Taylor, Assistant-Surgeon, S. O. 45, June 13, 1890, Division of the Pacific, is extended five months, on surgeon's certificate of disability, with permission to go beyond sea. Par. 6, S. O. 159, A. G. O., July 10, 1890.

Changes in the Medical Corps of the U. S. Navy for the two weeks ending July 12, 1890.

PAGE, J. E., Assistant-Surgeon. Ordered to hospital, Mare Island, Cal.

KENNEDY, R. M., Assistant-Surgeon. Ordered to the League Island Navy Yard, Pa.

RIXEY, P. H., Surgeon. Leave of absence granted for fifteen days.

OGDEN, F. N., Assistant-Surgeon. Promoted to be a Passed Assistant-Surgeon.

WHITE, S. STUART, Assistant-Surgeon. Promoted to be a Passed Assistant-Surgeon.

ATLEE, L. W., Assistant-Surgeon. Granted three months' leave of absence.

WOOLVERTON, T., Medical Inspector. Await orders to the U. S. S. "Philadelphia."

LOVERING, P. A., Passed Assistant-Surgeon. Await orders to the U. S. S. "Philadelphia."

MCMURTRIE, D., Medical Inspector. Granted leave of absence for thirty days.

CHOLERA INFANTUM A NEUROSIS.

BY ALEXANDER HARKIN, M.D., F.R.C.S.,
Consulting Physician, Mater Infirmorum Hospital, Belfast.

THE editorial article in THE TIMES AND REGISTER of June 14, with its portentous announcement "that twenty deaths from cholera infantum had occurred in Philadelphia during the previous week, and that the annual slaughter of the innocents had begun," warns me that I should, without further delay, fulfil a long-formed intention of requesting an opportunity, through the pages of that influential journal, of placing before its readers, and the American medical profession generally, a statement of my matured views and experiences upon the nature and treatment of choleraic disorders.

It is not often in medical literature that a writer feels justified, or possesses the moral courage to advance a statement that partakes, even in a moderate degree, of the nature of a pathological principle or law of disease; that he can trace the symptoms of allied disorders to a common source; that he can analyze matters of fact, general or elementary, show their actual relations to each other, and deduce from them an ultimate fact or principle; and, finally, sustain his hypothesis by appealing to the result of successful treatment founded on and in accordance with his published views.

The object which I propose to myself in this paper is to demonstrate that for the group of diseases—including cholerine, cholera infantum, choleraic or summer diarrhœa, cholera nostras, and Asiatic or epidemic cholera—having an unity of essence, an identity of nature, and a neurotic origin, there exists a common principle of treatment, and a reliable therapeutic remedy.

The publication of the death-roll from cholera infantum, and the free admission that the "annual slaughter of the innocents has begun," precludes the necessity, on my part, of commenting upon the inefficacy of the conventional treatment, followed by such painful results; these statements suggest the absence of sound etiological conceptions, and the want of a guiding principle of treatment deducible therefrom, and explain the apparent necessity that exists for treating symptoms when the disease itself may not be grappled with. Scientific medicine has suffered much from the incursions of novelties and the experimental methods of recent years. The ignis fatuus of the germ hypothesis has led men's minds astray from the sober path of clinical observation and therapeutic experience; and, while dazzled with the blandishments of bacillary investigations, physicians have too often ignored their chief duties—the alleviation of pain and the cure of disease. All must agree with the dictum of Virchow[1]: "that the discovery of the cholera bacillus, any more than that of the bacillus of tuberculosis, has not in the slightest degree contributed to the cure of phthisis or of cholera; while, by proclaiming through the agency of the microbe the infectious nature of these diseases, these speculatists have added another to their normal terrors.

I have always regarded cholera infantum, as well as Asiatic cholera, as a neurosis; indeed, Cullen, in his synopsis, has included both diarrhœa and cholera in the order Neurosis, and class Spasm; and Dr. Henry Maccormac,[2] whose pupil and assistant I was in the Belfast Cholera Hospital during the epidemic of 1834, taught that cholera was due to a lesion of the sympathetic system in the abdomen; and the results of my own observation and experience since that date have but

[1] Vide *Archiv Med.*, October, 1884, p. 173.
[2] Maccormac's Exposition of the Nature of Cholera. Belfast, 1832.

strengthened my conviction on this point. The opinion that choleraic disorders differ only in degree, and not in nature, is also held by many of the highest Indian and European authorities. Sir James Fayrer,[1] for instance, writes: "The fact is that cholera presents many phases and symptoms, varying in gravity from simple malaise to profound collapse; sporadic cholera is often spoken of as though it were a different disease to the Asiatic cholera. For my own part, I believe that *cholera* is *cholera* wherever it occurs, and its epidemic prevalence and intensity are phases or accidents in its history."

Dr. Guerin, at the Academy of Science, read a paper showing "that the distinction between different forms of cholera was purely arbitrary, the malady only differing in intensity. Dr. Dutricus Bey,[2] of Alexandria, asserts that the distinctions between Asiatic cholera and cholera nostras were but an arbitrary and artificial device," and Surgeon-General J. M. Cunningham,[3] in a recent report to the Governor of India makes a similar statement. As to the etiology of choleraic disorders, whatever the remote or predisposing cause, telluric or atmospheric, when in their actual presence I have at once recognized their neurotic natures, and treated them accordingly; the agency of the nervous system is apparent in every prominent symptom; the vomiting and purging evidently depend on derangement of innervation in the stomach and intestines; the spasms and cramps, the tremors, betray their nervous origin; and the symptoms of collapse, according to Claude Bernard, are dependent upon great irritation and hyperæsthesia of the sympathetic nervous system; while to the vaso-motor nerves may be accredited that depression of respiration and circulation, the most dangerous symptoms in this class of diseases. Assuming, then, that it is in reality the sympathetic nervous system that is at fault in choleraic diseases; it follows, that in seeking for a remedy, we should select one capable of controlling and influencing it. Thanks to modern physiological research, and clinical observation, that desideratum has been found in a cerebro-spinal nerve, the pneumogastric or vagus in the neck; it is found that when this nerve is properly stimulated, it immediately developes its inhibitory powers, equally in cholerine, as in the algid stage of spasmodic cholera. It is only necessary, in either case, to apply the liquor epispasticus of the British Pharmacopœia with a camel's-hair pencil in a narrow stripe over the sheath of the pneumogastric in the neck, extending from the mastoid process to the angle of the lower jaw. The effect is almost instantaneous, the purging, the vomiting, and cramps immediately cease, the patient generally falls asleep, and awakens cured, long before the vesication is complete. Stimulation of that part of the sympathetic nerve going to the heart, is followed by increased forcible contractions, but stimulation of the vagus going to the heart may cause its stoppage in complete diastole. Counter-irritation over the vagus also restores the cardiac inhibitory functions of the nerves so often in abeyance in choleraic illness; through its influence the violent contractions and palpitations of the heart are subdued, the dilating power of its walls and cavities, especially of the left side, is restored, and the stasis of the pulmonary and arterial systems is put an end to. In extreme cases, the rapid action of the galvanic current might be invoked with advantage, meanwhile I have latterly discarded every auxiliary measure, and depended alone on the topical remedy. One collateral advantage in its application is, as Doctor Harry Poole Berry, of Grantham, Lincoln, observes, "that it is at any rate a method of treatment which is attended with no risk, and in no way interferes with any other treatment which the practitioner may see fit to carry out." And so, to the timid or cautious practitioner I would add, for the nursling or the adult total ablactation is necessary, as there is nothing so irritating to the intestinal tract in choleraic troubles, as the casein contained in the lacteal secretion, whether human or bovine. As a substitute arrow-root boiled in water, with the addition of port wine, condensed milk, beef tea freed from fat, and starchy foods, may be given; as beverages soda water and iced water, barley water, a weak solution of chlorate of potash; as a galenical dilute sulphuric acid holds the first place; rest in bed with every appliance capable of maintaining bodily heat in trunk and extremities, turpentine and mustard epithems, are useful auxiliaries; but the one thing *indispensable is the counter-irritation over the vagus.*

In the actual presence of an epidemic where every practitioner may, without much trouble, satisfy himself of the value or otherwise of my teaching, much corroborated evidence is not so necessary. I shall, however, as customary in any new departure, adduce a few examples and proofs of its efficacy; and, in the first place, from an English physician, personally unknown to me, Dr. Berry, already quoted; who stated in writing to the editor of the *Lancet* on October 7, 1885: "I have tried the external application in the manner described by blistering behind the angle of the jaw in at least twenty cases, which were more or less severe, and occurring in patients from infancy to old age. In all the cases it has been attended with marked and immediate success, the vomiting and diarrhœa being controlled almost at once, and in some of these cases I had previously tried acid and opium, catechu, chalk and logwood in usual doses."

Cholera Infantum.[1]—On September 24, 1884, I was summoned to a child, living in Upton street, Belfast, aged twenty months, and saw her at 11.30 P.M. I found the child lying prone on the mother's knees, with its arms and legs lying listlessly on either side; it was cold and feeble, and almost pulseless, and was vomiting and purging at the same time. I was informed that the child had sickened at 6 P.M., same evening, and had vomited at least every quarter of an hour, till my arrival. The mother had, previously to my visit, administered milk and lime-water, without any benefit. I did not prescribe any medicine, but, having placed the child on its back, I applied the blistering fluid behind both ears and on its neck. Soon after the application the child fell asleep, and, after the expiration of half an hour, I left for the night. Calling at 10 o'clock A.M., next day, I found the child in its mother's arms, quite lively and well; neither vomiting nor purging had returned.

Cholera Nostras.—Constable C. sent for me to Queen street Police Barracks, on 18th September, 1883, at 8.30 A.M. I found him in the act of vomiting, with small quick pulse, violent cramp, forcible palpitation of the heart, great debility, fainting, and coldness of the extremities. He was purged at frequent intervals, and the dejecta were of the usual rice water character. He said that when on duty in the police cells, he was attacked with profuse vomiting, followed an hour af-

[1] On the Origin, Habits and Diffusion of Cholera. By Sir J. Fayrer, K.C.S.I., M.D., F.R.S.

[2] International Congress of Hygiene, September 1, 1834. *The Hague Lancet.*

[3] *Lancet*, July 28, 1884.

[1] *Vide Lancet*, August 16, 1884. Art. Cholera.—*A. Harkin.*

ter by violent purging and cramps; an attack occurring about every fifteen minutes. I did not prescribe any internal or external medicine, but painted him at once in the hollow behind the ears, down as far as the angle of the lower jaw, with the liquor epispasticus B. P., assuring him at the same time that he would not have any recurrence of the symptoms. I visited him again at 10.30 A.M., and found him convalescent, not having had either sickness or purging, as I had predicted.[1]

Epidemic Cholera, Malta,[2] reported by Dr. Inglott, District Medical Officer. Giuseppe Galt, forty-two years of age, shopkeeper, residing at Vicolo, San Francesei, Zabbaz, assisted his wife with great assiduity; his wife refused to undergo the vagus treatment, and died from spasmodic cholera thirty hours after the attack. After four hours from the death of his wife the husband was seized with violent diarrhœa, I was called to visit him at his residence. The following are the symptoms which I observed: Diarrhœa very intense (rice water), vomiting, eyes very hollow, lips violet, body cold, voice feeble, pulse weak, respiration disturbed, sense of oppression, thirst intense, cramps very severe in the lower extremities, general debility, suppression of urine.

Treatment: Injections of ether; vesication very strong over the vagus on both sides of the neck. After two hours I visited the patient again, and found that he had slept nearly one hour; cramps stopped, pulse became active, diarrhœa suppressed, passed urine freely. I called again to visit the patient in the afternoon, and found him weak, but recovered. The vagus treatment acted like magic!

This case is one of many, cured in the cholera hospitals of Malta, and reported by Drs. Inglott and Cannataci, during the epidemic of 1887. Dr. Inglott adds: "I have no hesitation to state that Dr. Harkin's treatment is a remedy both reliable and speedy in its action, in all severe cases of cholera."

I need not multiply instances; I have thus submitted proofs of the curative power of the simple remedy in the three great phases of cholera; as all are in the same category, the evidence of its efficacy in either case affords corroborative proof of its beneficial influence in the others; and I conclude by commending this paper, hastily compiled, to the kind consideration of my American medical brethren.

MOUNTAIN FEVER.

By WILLIAM TREACY, M.D.,
HELENA, MONT.

SEVEN years ago I located in Montana for the purpose of practising medicine. Upon inquiry, I was informed that the most prevalent disease was a separate and distinct type of fever called mountain fever. I had practised medicine in Indiana and in Chicago, Ill., and was familiar with typhoid, remittent, bilious, and typho-malarial fevers, and expected to find something new and different from any one of them.

Mountain air, I was informed, would not permit the typhoid germ to exist; that all "pilgrims," as recent arrivals are called, must necessarily have mountain fever before becoming acclimated.

As a rule, the pilgrim, on coming to the mountains, has an appetite that would need the digestive apparatus of an ostrich; an excessive quantity of food is taken, and the digestive apparatus upset.

The summer and fall months are the fever months. During the months of July and August the temperature is often very high, frequently 105° in the shade, while the evenings are quite cool. Improper clothing is worn, and the sudden changes predispose to chill.

During the time that the Northern Pacific, the Great Northern and branches were being constructed, a large number of men were employed as graders. These employés were chiefly foreigners, and lived like cattle herded together in tents, dugouts, and rudely constructed log-cabins, sometimes forty or fifty bunking in the same small tent or cabin; they were careless about their food, and uncleanly in their habits. A great many cases of so-called mountain fever developed among those employed on the railroad work, usually a remittent type, commencing with lassitude, loss of appetite, pains in limbs, very severe constipation, headache and backache, followed by a chill (not as well marked as in pneumonia) within twelve hours, and rapid rise of temperature soon after chill, usually 104°; heavy white coating on tongue, and bitter taste in the mouth; very restless and always unable to sleep, unless large doses of bromide are given. The difference in morning and evening temperature is usually two degrees. Fever yields nicely to treatment, and patients usually recover in about three weeks. The death-rate is small in uncomplicated cases; about two per cent.

Then, we have many cases of typical typhoid fever, with varied symptoms, and, I believe, modified by elevation and pure air. In these the invasion is gradual, tired feeling, accompanied by chilliness, dullness, epistaxis, diarrhœa, abdominal tenderness, gurgling in right iliac fossa, tympanites, rose eruption and hemorrhage of the bowels, bed sores and cellulitis, and sometimes intestinal perforation and death, unfortunately the same as you do in the lower altitudes.

During 1885 they had a number of undoubted typhoid cases in Deer Lodge, in this State, contracted from drinking water. Upon investigation the water was found to have been contaminated by seipage through a gravel subsoil from water-closets in close proximity.

At Helena we have an excellent system of sewerage, and consequently few cases of typhoid; but a great many cases occurred last year among the men engaged in digging the trenches for sewer pipe.

We are still looking for "mountain fever" that is a distinct, specific form of fever indigenous to mountain regions only; thus far we have found as the nearest approach to it, according to the information given us about it, the usual remittent type, modified of course by the great amount of ozone in our altitude, differing in no respect from the remittent fever found in the East, and yielding to treatment in much the same manner; and, I think, my medical brethren in the East will agree with me in declaring the much-talked of mountain fever to be a myth, or, at best, a term improvised by the frontier settlers for our old-fashioned, familiar, every-day remittent fever, so well known to Eastern practitioners.

REPORTS FROM ST. PETER'S HOSPITAL, HELENA, MONTANA.

George Benedict, aged twenty-five. Dr. Treacy. Gunshot wound. Compound comminuted fracture of femur at trochanter. Accident occurred on Wednesday, September 27, 1887; patient arrived at hospital Sunday, October 2, having travelled during that time, by boat, stage and train.

Wound irrigated with sol. bichloride mercury, 1 in

[1] *Vide Lancet*, August 16, 1884. Art. Cholera.—*A. Harkin.*

[2] The Vagus Treatment of Cholera in Malta, 1887. By Alexander Harkin, M.D., F.R.C.E. London, Bingham, Strand.

5,000 to 7,000, five times during twenty-four hours; moist dressing applied; drainage-tube.

Patient developed enormous bed-sore second day after admission to hospital; removed to canvas cot with a hole cut in it, through which to dress the bed-sore, and another, through which to dress the wound. (Impromptu surgical bed). Discharged May 14, 1888; complete cure. Temperature did not rise above 101° during entire stay in the hospital.

Brady Hanson, January 16, 1889. Dr. Treacy. Fell down shaft, ninety-two feet. V-shaped cut in forehead, requiring sixteen stitches, two through the cartilage of the nose, four through upper lip, and three through the lower lip—twenty-five stitches in all; no anæsthetic. Discharged cured, February 2.

Isaac Loftus, January 16, 1889. Dr. Sligh. Victim of giant-powder explosion; double amputation; right arm taken off just below elbow, left hand disjointed at wrist; six stitches in lower lip. Operation performed by Dr. Sligh, assisted by Drs. Cole and Dean. Discharged May 6. Stumps healed, ready for artificial hands; no abnormal temperature.

James Letcher, April 18, 1889. Dr. Treacy. Cellulitis of hand; little finger amputated at Elkhorn, by Dr. Brooke. Incisions made and injected twice daily; peroxide of hydrogen used. Discharged cured, June 9.

P. J. Cunningham, June 24, 1889. Dr. Treacy. Suppurative synovitis of knee; incision made; drainage-tube introduced; irrigated daily with sol. bichloride of mercury, 1 in 5,000. Discharged cured, August 19.

Charles Buell, June 26, 1889. Dr. Treacy. Lacerated wound of hand, done with circular saw; third finger amputated at second joint July 15; left July 31.

Frank Siple, July 12, 1889. Dr. Treacy. Brakeman, Northern Pacific Railroad. Seven cars passed over his arm. Amputation just below shoulder—Dr. Treacy, assisted by Dr. Barbour. Patient got up and dressed July 19; transferred to railroad hospital at Missoula, July 21. Discharged, stump healed, July 31.

Mrs. Young, Feb. 4, 1890. Dr. Treacy. As far as could be learned, patient had pleurisy, right side, a result of la grippe, at her residence, seventy-five miles out, two weeks prior to entering hospital. Dr. Treacy made a diagnosis of pleurisy with effusion, and wrote her husband in order to gain his consent to operation. Patient died two hours before his arrival, Feb. 8. Heart failure, result of journey.

John Clark, Dec. 28, 1888. Dr. Treacy. Patient presented appearance of pneumonia on admission to hospital. Dec. 30, developed rötheln. Jan. 2, a decided case of pneumonia; convalescent Jan 15. Jan. 22, pleurisy with effusion, right side. Jan. 23, aspirated, ℥xxiv fluid drawn off. Jan. 30, incision made and drainage tube inserted. Discharged cured, March 2.

Henry Meyers, aged forty-five, Jan. 16, 1889. Dr. Treacy. Feet and hands badly frozen; line of demarcation appeared just below ankle-joint. Jan. 23, double amputation just above ankle joint. Dr. Treacy, assisted by Drs. Dean and Pleasants. First and middle finger of right hand taken off at second joint; also first of left hand. June 11, patient put on a pair of Marks' artificial feet, and left hospital July 1; no high temperature after operation.

Hugo Freyler, Feb. 6, 1888. Operation for empyema; drainage-tube inserted by Drs. Cole and Sligh. Discharged cured, March 26.

James Murray, aged twenty-one, Northern Pacific newsboy, cerebro spinal meningitis. Dr. Treacy. April 8, 1888. Very delirious first three weeks; could not be kept in bed; diarrhœa set in; continued remaining three weeks of his life; twelve to fourteen stools in twenty-four hours, resembling chopped spinach. Died, May 18.

Frank Disreau, French, wood chopper, April 7, 1888. Dr. Treacy. Incised wound of leg. Wound did not heal; on investigation it was found that it had been sewed up with cord and wire. Cellulitis. Wound opened up and drainage tube inserted; irrigated twice daily. Hot fomentations kept up for a week. Discharged cured May 6.

Martin Westfall, aged forty-six, May 19. Dr. Sligh. Froze his foot in January; amputated first joint of little toe himself; entered hospital May 19, 1888; foot badly swollen and inflamed. Dr. Sligh amputated large toe and remainder of small one, May 26. Still the foot did not do well. Amputation made above ankle-joint, by Dr. Sligh, assisted by Drs. Atchison and Barbour, June 6. Left hospital August 15. Stump healed. Syphilitic history.

Harry Sherman, aged eighteen, May 18, 1888. Dr. Treacy. Inflammation of knee-joint. Hot fomentations applied to knee until May 21, when incision was made and drainage tube introduced. Chill daily, followed by a temperature of 103–104°. Pulse 110 to 120. Flow of pus profuse; constant diarrhœa, which, when checked, caused increased flow of pus, and vice versa. Patient fearfully emaciated. August 24 Dr. Treacy injected peroxide of hydrogen; flow of pus lessened; used the peroxide H. daily, with good result; fever checked; appetite returned; patient gained flesh. In ten days pus had ceased and wound was healing: patient walked on crutches September 3. Left the hospital cured, October 14; traveling to Beaver City, Nebraska.

Henry Deffauld, June 30, 1888. Dr. Treacy. Caseous abscess. Patient complained of pain in his thigh for two years. Had struck it with a rock the day of entry to hospital. Incision made and drainage tube inserted. Temperature 102° to 103°. Wound irrigated daily. Discharged August 20.

Vivian V., aged three years. Dr. Treacy. Empyema, right side. Opening made and drainage tube inserted. Iodide of iron internally. Discharged October 4.

Florence D., aged eighteen, November 9, 1888. Dr. Treacy. Operation for necrosis of the femur. Popliteal space opened; sequestrum three inches long and detached. Opening packed with iodoform gauze and allowed to heal from the bottom. Iodide of iron internally. Peroxide of hydrogen injected in wound daily. Irrigated with bichloride of mercury, 1 in 5,000 to 7,000 daily. Discharged cured, November 28.

John F., September 18, 1888. Dr. Treacy. Com-

E. D. Ludlum.

* Discharged.

pound comminuted fracture of inferior maxillary. Used metal splint and bandage; carbolized wash for mouth. Discharged October 6, cured.

E. D. Ludlum, October 30, 1888, Northern Pacific express messenger. Dr. Treacy. Typhoid fever. Subsultus tendinum; characteristic diarrhœa; delirium followed by coma. *Treatment:* Quinine 5 gr. every three hours during the day; 30 gr. on rise of temperature in the evening. Egg-nog three times daily. Alcoholic sponges. Discharged cured, December 5. (See table, p. 76.)

Crampton Linley, typhoid fever. Service of Dr. Treacy. Bloody diarrhœa; subsultus tendinum; no delirium; stupor. Discharged cured, March 12. *Treatment:* Quinine, gr. x, and repeated in one hour when fever was high. Nitro-muriatic acid dil. gtt. x, and quinine, grs. v, every three hours. Dover's powder, gr. v, at night when restless.

Crampton Linley.

ELECTRICITY IN ITS MEDICO-LEGAL RELATIONS[1].

By CLARK BELL, Esq.,
President of the Medico-Legal Society of New York, Honorary Member of the French, Belgian, and other Societies of Medical Jurisprudence.

THE advance in scientific research and discovery, within the last five years, in the application of electricity to the wants and needs of mankind, has been something prodigious.

One can hardly keep pace, with the advancing strides of electrical invention and discovery.

The electric light is now a public necessity, and is in almost universal use, in cities and large towns.

Electricity, as a motive power and force in mechanics and engineering, is coming into a prominence and usefulness, that is beyond the comprehension of those who have not investigated the subject.

Perhaps no form of use, of that energy known as electricity, at the present hour, excites greater public interest, than the problem of electric lighting and its relation to the public good, and especially to the public safety.

The practical use of this agent, for lighting as well as for the telegraph and telephone, must be by wires through which the current is conducted.

The electric telegraph, which created the pioneer road for the passage of the current, was along wires suspended in mid-air.

That path and lead was followed, usually, as the advance of discovery; and the applications of practical inventions brought the agent into new and untried fields, but usually along this pathway.

In America and Great Britain, countries that occupy the lead in this development, the overhead wires came almost naturally into universal use, and without regard to the power or potency of the current employed.

The advancing wave of this practical use brought into requisition, greater force and greater potency; and the experiments, developing various kinds of currents, led to new problems and complications, which found their way to the public eye and ear soonest, in the systems of electric lighting as applied and used in the great cities.

Municipal authorities start with the legal proposition, that the power of regulating the use of any agent, as steam, electricity, or any other energy used, so far as it relates to the public safety, is, and of needs must be, the subject of municipal regulation, or legislative enactment.

The earlier experiments, and indeed the practical uses of this wonderful agent, while—known to be dangerous, were singularly and almost marvelously free from disaster in this country, and, so far as we have been able to learn, throughout the civilized nations of the world that employed it.

The accidents, fatal or otherwise, attending or resulting from its use, were less than from any other energy used by mankind in the arts and sciences or as a force, not merely in actual number, but in ratio to the total number of those directly engaged in the use.

The number of deaths or accidents resulting from fire, steam, gas, or other forces, exceeded those from this agent so greatly, that these latter became absolutely insignificant in fact, both in the popular estimation of America as well as of Great Britain.

A different impression obtained in France, and, indeed in all Continental countries, save perhaps Italy.

In Paris and Berlin, the authorities compelled all wires to be placed under ground, by the electric lighting companies.

This was not due to considerations of public safety, so far as danger of life was concerned, in either city. The German regulations do not seem to contemplate personal danger, as low one hundred volts potential are about the powers used, and dangers of fire are regarded as more likely, and precautions of insulation as more necessary, where the continuous current is being generally used.

This is also true of Belgium, but only partially true of Italy, where the low potential powers are generally in use for lighting, but an extraordinary exception is contemplated for the use of enormous power, at the Tivoli-falls outside Rome.

The plan is said by Sir William Thompson to be, to use two thousand five hundred horse-power at the Falls; this to be transmitted by alternating currents, at five thousand volts, by overhead wires, to the Imperial City, a distance of thirty-seven kilometers; then to reduce it by a transformer to one thousand volt currents; and then distribute it underground, by numerous transformers, in different parts of the city and to consumers, in one hundred volt currents, for general public use.

The tendency of legislation has been to put the wires underground, on the theory that the question of danger from high pressure overhead wires might be thus either avoided or reduced to a minimum.

The British Electric Lighting Act, of 1888, seems to have been based upon that presumption.

The public sentiment in New York, at the present moment, is strongly in the same direction; and it is intensified by the darkness which came upon that city, since the action of the municipal authorities, in demolishing the overhead wires, under the guidance of the Inspectors of the Board of Electrical Control of the city, to the extent, as we are advised, of at least one-fourth of all the mileage of the electric light wires of the city, and with the result of suspending

[1] Read before the Medico-Legal Society of New York, and before the American Medical Association at Nashville, Tenn. (From advanced sheets of *Medico-Legal Journal.*)

the service of at least nine-tenths of all the arc lights of the metropolis.

This was a great public calamity for New York, and must have been attended with enormous loss to the corporations who had supplied the light; it was certainly an enormous inconvenience to the general public.

The agitation of the public mind is so great, that we think it wise now to look at the question with conservative regard for the truth and with more of calm reflection, and without that excitement that resulted in such a wholesale destruction of the plant of the various companies that supplied the city.

Let us inquire as to what currents are now used, and look at the relations of each to the public safety, and examine what precautions are necessary and how they can best be taken.

Mr. Thomas A. Edison, a very high electric authority, has classified these currents as follows:

1. The low tension continuous currents, with a pressure not exceeding two hundred volts, used for incandescent lighting.
2. The high tension continuous current, with a pressure of two thousand volts or over.
3. The high-tension semi-continuous or pulsatory current, with a pressure of two thousand volts and over.
4. The alternating current, with a pressure of from one thousand to three thousand volts and over.

(*Electric Engineer*, January, 1890, page 16.)

Sir William Thompson is an authority for the statement:

"That one hundred volts in the house is perfectly safe to the user, whether the current be alternating or continuous, as is proved by large and varied experiences in England."

(*North-American Review*, February, 1890, page 191.)

This statement is quoted approvingly by George Westinghouse, Jr., a man of large and varied experience and practical knowledge, who has recently taken high rank as a writer upon these questions: "What is true of England, of Belgium, of Germany, and the Continental cities, I think we may say is quite true of the City of New York."

Perhaps the clearest definition of the "alternating current," or rather the characteristics of that current, and the "continuous current," as contradistinguished from each other, is that given by Mr. Geo. Westinghouse, Jr., in the March number of the *North American Review*, in his able and forcible reply to Sir Wm. Thompson's article on "Electric Lighting and Public Safety."

Mr. Westinghouse says:

"It is now quite generally understood that, in the generation of electricity for electric lighting and similar purposes, a coil of wire with united ends is caused to approach a magnet, by which operation a pulsation of electricity flowing in a definite direction is produced in the wire; and, when the coil is withdrawn from the magnet, another pulsation is produced, but this time in the opposite direction. The repetition of this operation produces a succession of pulsations, alternating in direction, which is termed an alternating current; and, in what is known as the alternating system of distribution, these natural currents are used in the distributing mains directly as they are produced by the generator.

"The production of what is known as a continuous current involves the changing of every alternate pulsation by a complicated mechanical contrivance, called the commutator, which, through two sets of brushes—one set taking all the positive currents, and the other all of the negative—causes the successive pulsations all to flow in the same direction, constituting what is technically termed a direct current, and usually spoken of as a continuous current. This current is similar in character to that generated by the well-known chemical batteries."—*North American Review*, March, 1890, p. 323.

One characteristic of an "alternating current" is, as described by Mr. Westinghouse:

"That an alternating current, when made to traverse a coil of wire, is capable of inducing or creating, in an independent coil of wire in the neighborhood of the first coil, a similar alternating current of equal energy, but capable of having its pressure or its quantity modified to any required extent—a result which the continuous current is utterly incapable of producing."

It is claimed also by Mr. Westinghouse that absolute safety is secured to the consumer, both as to personal injury and as against fire or other accidents, by using, even with very high voltage in the street mains, well secured and protected, wholly disconnected with the house wire, supplied by converters or transformers, located in or near each building, composed of two separately wound and insulated coils, one of thin wire connected with the street mains, and the other of thick wire connected to the wires of the building. The practical working of this arrangement is that the voltage, which may be two thousand in the thin wire, induces in the neighboring thick wire an equivalent amount of electrical energy, but so modified as to be only fifty volts in the thick coil, the volume of the electricity being as many times increased as the voltage is diminished.

It would seem that suitable legislation or municipal regulations could be made, that would prohibit any connection between the consumer and the high pressure mains, that would reduce the danger of personal injury to the minimum, so as to be substantially safe.

Electrical engineers and experts should be called to pass upon the questions:

1. What precautions could be taken to reduce the danger of injury to persons from the use of high pressure main wires, whether submerged in great cities or suspended in the air outside city limits?
2. What precautions should be adopted in the distribution of the light by transformers, so as to make the consumers absolutely safe as to personal injury?
3. What quantity can be carried over each class of conductors, and what regulations and limitations as to quantity, should be placed on each class and kind of conductors?

The use of the alternating currents of high tension, by means of transformers, which convert or change the current into low tension currents, and the absolute disconnection of the two systems of conductors, are not only generally recognized by electricians, but are in practical working operation in the chief cities of the world.

The danger to public safety from the use of either current may be then stated to be, in addition to personal safety, that of causing or occasioning fires and of explosions, and it seems quite clear, from the best authority, that placing the main high pressure wires underground does not guard against either of these dangers.

Mr. Edison has cited an incident that occurred near the corner of Wall and William streets, New York, by the crossing of wires at a pressure of only one hundred and ten volts, which caused energy "sufficient to melt iron tubing and reduced the paving stones to a molten mass;" and it is apparent that burying the wires, without important modifications of the present regulations, would not be a certain safeguard against danger to the public safety in this direction.

Mr. Westinghouse correctly states the source of danger as to fires when he says:

"Electrical fires are the results which are due directly to the quantity or volume, and not the tension or pressure of the current.

"The welding together of massive bars of iron is quickly and perfectly accomplished with an electrical pressure of only one volt, although the volume of current is, of course, enormous."

Again: while no injury to person would result from an electrical pressure of one hundred volts or less, a fire can be started between two wires with a hundred volts of direct current, by the moisture from water, which a pressure of fifty volts of the alternating current could not do.[1]

Assuming the correctness of this proposition, this fact would teach us how to avoid fires, by disconnecting the building from the high pressure mains, and substituting transformers for supply to fifty volts, thus making fires from this source practically impossible.

It would be needless and perhaps unwise, in the present agitated state of public opinion, intensified by the few fatal cases (but in several very terrible to contemplate, a few of which greatly inflamed the public sense) to attempt to change popular dislike or distrust of the overhead wires: but it is nevertheless quite true, that, unless provisions are made and regulations modified, to suit the public exigency, the total submerging of all the wires under the present regulations may result in New York in greater public harm, than any yet sustained, as the ratio of loss of life was so small in its ratio to death from other causes.

The characteristics of the different currents furnish an interesting study when considered as to their respective potencies, in regard to personal safety, when passed through the human body.

The most important recent contribution to this branch of the subject, is that presented by Dr. Arthur Harris and Mr. H. Newman Lawrence, in a recent paper submitted to the London Institute of Electrical Engineers, upon the question of the relative potencies of the alternating and continuous currents, for mischief to human life.

The general summing up of their admirable group of experiments indicate, that the resistance of the human body was seven times greater with the continuous than the alternating current.[2]

The testimony given by electrical experts, before the Legislative Committee of Investigation, is full of interest upon this branch of inquiry.

It may be regarded as an indisputable proposition, that where it is desired to produce fatal results as in the case of executions under the law, the alternating current is by far the most reliable and certain in its fatal effects.

Mr. Edison, that high electrical authority, in answer to the writer's inquiry, as to whether there was room for reasonable doubt, as to the certainty of death, by the instrument which had been selected by the public authorities, to carry into effect the sentence of the tribunals of those condemned to death, in the State of New York, stated that "death would be instantaneous and certain beyond any peradventure—with the present instrument."

The question of electrical executions as a penalty or punishment for crime, is outside the previous considerations.

If electrical scientific knowledge is desired, to consider what method is the most certainly fatal to human life, by a direct application for that purpose, we should hesitate to believe that any competent expert would fail if he made a serious effort to accomplish that result by the alternating current.

The application to legislative interference, naturally waited until the Court of Appeals, passed upon the constitutionality of the law itself.

It is said that revolutions never go backward, and the signs of the times are not favorable to going back again to the hangman and the scaffold.

The relative merits of this method of executing criminals, will be considered by our people, and its merits and demerits canvassed.

I should sooner look (if any change came in the present law) to the abolition of the death penalty in this State, rather than to a restoration of the scaffold and the rope. Indeed, this is the form which opposition to existing laws took, before the Legislature, in the bill to abolish the death penalty for crime. And that side of the discussion was presented with great force, and the measure passed the lower house of the New York Legislature. There has been a strong minority in this State opposed to the death penalty for crime for some years. This minority will now be reinforced, by those who have opposed the new law, and the issue came before our people in the Assembly bill. The leading judges and jurists opposed the abolition of the death penalty, and, in the debate before the Medico-Legal Society on May 14, no speaker favored the abolition, though there are members of the body who do.

The medico-legal aspects of this wonderful energy are at the present moment attracting the attention of courts, jurists, and legislatures; and this is my apology for bringing these considerations to public notice.

DRIFT OF AMERICAN MEDICAL JOURNALISM.[1]

By T. D. CROTHERS, M.D.,
Editor, Journal of Inebriety, Hartford, Conn.

ANY general comparison will show that medical journalism in this country is in advance of that of Europe. Simply because it represents more fully the current thought and medical progress of the times. The best European journals are often narrow, critical, and morbidly conservative. In many of them there is a tone of completeness, and assumption that the science of medicine is understood and settled.

New truths are innovations, unwelcomed unless supported by some old university prestige.

The daring explorer who brings new views from the frontier of science alone is met with icy suspicion and reserve.

American journals are sometimes narrow, but never critical or morbidly conservative. They are often recklessly generous and broad, and intensely personal; but, with very few exceptions, there is manifest a spirit of expectancy, and welcome to all new truths, from any source.

European journals rarely print the latest facts of scientific study. Such facts must appear in a book or pamphlet, then the journal will pass judgment. The most advanced work of medical scientists must be published and go on the market, and create an interest in the subject and demand for itself—then the journal makes a record of it In this country the medical pioneer is sure of a hearing in the journals from the beginning. No matter how revolutionary his conclusions may be, he will always have an organ in the medical press, and an audience to endorse or condemn his work. The medical leader in Europe must reach his audience through a volume, and his work is seldom fully realized in his life-time. Often such leaders become narrow and dogmatic, and intensely combative.

In this country the medical man who believes he

[1] Read before American Medical Editors' Associations, at Nashville, June 20, 1890.

has discovered some new facts obtains a large, critical audience through the medical journals at once, and his work is consigned to oblivion or put away for further consideration. After it has been the rounds of the press, and become the common property of the profession, he may gather it up into a book form, which generally dies with the first edition.

But long before this it has served its purpose, and has been a silent power, both by suggestion and stimulating to clearer and more accurate study.

In this respect alone the American medical press excels, by giving wide and rapid publicity to every new advance in medicine. In Europe the latest facts of science are found in books and pamphlets. In this country they are scattered through the journals. If medicine was a fixed science, based on fixed facts, the former medium would be superior.

But as it is not, the latter is the true evolutionary method of growth and progression.

The most general history of medical journalism points to a psychical line of march that has escaped attention.

The phenomena of the physical in the realm of medicine has absorbed the entire attention, so far, and all study and effort has been to classify and reduce them to laws; while the realm of the psychical has been ignored or left to quacks. In medical journals seen from a psychological side, there is clearly an ebb and flow of scientific thought that has a certain tendency and drift which may be seen in part.

The future of medical science is not a closed book. Everything in the present is largely a prognostication for the future.

Medical science of to-day, and its representation in the journals, turns largely on an accurate knowledge of the past and present.

Every journal in some degree exhibits forecasts and intimations of the coming medical science, of its coming teachers, and its coming journals.

The confusion and hurry of the present obscures the fact that with all the development and progress of to-day we have scarcely come to the threshold of the reality of the science of healing. The real work in medicine is away before us, like misty outlines of far-away mountains.

All the energy and enthusiasm of the past and present are preliminary, merely clearing away the ground and preparing for a comprehension and utilization of the majestic laws of evolution and devolution. The real science of medicine is away in the misty dawn of the future. But already there are outlines of great realms of surgical possibilities—of possibilities in preventive medicine; of chemical possibilities in foods and nutriments; of physiological and psychological forces, the use of which will revolutionize all our past theories and practice.

The boasted achievements of to-day are literally a series of failures to comprehend the whole truth; but failures that rouse renewed energy and study, and finally marks the journey that leads to larger, clearer views.

The history of medicine, both in the past and present, is the evolution of mind and thought, the hurried march from the lower to the higher. Thus, every year the range of the senses and the reason widens and the incomplete grows less, and the unknowable narrows.

This is the shifting panorama that medical journals are trying to present. The procession of medical journals is coming and going, and each one announces itself with that trite expression as meeting a "long-felt want," which is literally an unconscious reason and apology of a psychical need and demand that, like Banquo's ghost, "will not down." Each new journal, no matter how sickly its infancy and short its life, is the unconscious expression of this need; it is the pushing forward toward an ideal; toward a type of larger, better journals in the future.

The multiplication of journals of all degrees and qualities is not a matter of whim or accident, but is in obedience to pyschical laws and forces that are largely unknown.

The significance and meaning of this almost precocious birth, growth, and death of medical journals is dimly apparent in many ways.

Thus, each new journal brings with it new writers, and new interest into journalism and its work; new conceptions of facts, and their relation to truth; new groups of readers and authors, and new personal interests; new aspirations, to shape and mould the literature. Each new journal is an educational force in the circle in which it lives—it starts men thinking; it rouses them to put their thoughts on paper; it makes them more careful readers, and stimulates comparison.

There is a certain drift and tendency in this increasing tide of journalistic literature toward a clearer and more accurate knowledge of diseases, and their prevention and remedies.

The more journals published the more rapidly the elimination of the weak will go on, and also the growth of the survivals.

Every journal builds up a certain number of readers, who very quickly outgrow the influence of the journal—unless it keeps pace with the times—and who demand a better journal, and assist in killing the old. The field of journalism is filled with instances of hearty support and active laudation in the early life of journals, soon followed by neglect, condemnation, and death. The readers have outgrown the journal. The long-felt want is simply increased by such journals. A financial support may sustain a weak journal for a time, but even this will fail. A journal depending upon brain capacity and culture will live for a time; but brain capacity and culture must be replaced or the journal dies Consolidation and concentration of journals may lengthen out the life for a time, but the remorseless law of the survival of the fittest crushes out and levels up all thing at last. While the *drift* of American journalism is upward, toward higher types and clearer, more accurate views of medical science, it is evident that all advances of science in the future will come before the profession first in the journals.

Medical journals are clearly destined to be the sole historians of all scientific progress. Already, in this country, they are far on the road in that direction. In proportion as they fail to realize this they fall into graves of their own digging. There is also a marked increase of the scientific capacity and sense of facts and the laws which govern them in American journals. Observe this in the papers and lectures of an increasing number every year. Formerly wordy arguments, statements, and theories, loaded down with quotations equally uncertain, comprised the bulk of the papers. Now the best journalistic work is the presentation of facts and the most reasonable conclusions which they indicate. The reader follows such a presentation with keen interest, because it appeals to his reason. On the other hand, mere statements and theories appeal entirely to his faith and credulity.

The journal must rouse and stimulate the reader; not soothe his convictions and lull him into belief of the finality of supposed truth.

The evolutionary progress of all branches of science is revolutionary. All truth is but present appearances, which may change materially to-morrow.

True journals can have no fixed theories or conceptions that are not open to question and doubt, and to the consideration of any evidence that may be offered.

While the American journal is often lamentably weak and sickly, and dies early, or is an imitator of the secular press—without scientific capacity to realize facts and the laws which govern them—there is a vivacity and power of adapting itself to every new advance, defending or condemning it with eager earnestness, that places it far beyond all foreign journals.

The American medical press leads all the world to-day—not in journalistic culture or solid, logical comments and essays on medicine, but in progressive appreciation of the incessant changes and forward movement of science.

The evolutionary march of medical literature and journals is nowhere more clearly apparent than here.

The most revolutionary theories and startling views have defenders in journals. While both theories and journals die, they leave an impress that contributes, in some measure, to the growth of science. Thus medical journalism is on the road, passing through the great upheaval periods, epochs of dogmatic fog speculation, periods of egotistical conservatism and mutual admiration, and hero worship of foreign authors, followed by fiery personalities, and long levels of subsidence. But through it all there is a grand advance, a movement, an approach toward a clearer knowledge of the laws which govern the growth and decay of all matter. As in nature, it is the same struggle, and the survival of the fittest, and even these are soon replaced by others more fit.

The drift of American journalism is the drift of all science—upward, outward, and forward. The constant advance from the old to the new, from the best and clearest facts of yesterday and to-day on the larger truths of to-morrow.

The more fully we comprehend this fact the better our journals will be. Failure to realize and act upon this is inevitable failure, irrespective of all other conditions and surroundings.

The literature and practice of medicine, as well as the physician, are more and more largely influenced by journalism. The power of the treatise and book are growing less and journalism is widening, until it now includes special journals covering every branch of medicine.

Our journals and our associations are fast becoming great central forces, that will either lead the march of medical science or be crushed out by it. Popular favor or financial support are powerless to sustain a journal that is out of the drift of scientific advance. Every year the medical profession is growing, and every year a better class of journals is demanded. The question comes to us from all sides: Are our journals growing to meet this demand? Do we realize that medicine, as a science, is passing through a great drift period? Do we realize that medical literature is more and more intimately associated with journalism? That journalism is unconsciously leading all medical literature? That every advance of medical science depends upon journalism in its highest development? The more accurate and better the journal the better the scientific work.

Journalism demands our best efforts, not our leisure moments after the professional labors of the day. Journalism demands a progressive growth from year to year, not only in new facts and methods of presenting them, but in the individuality of the journal.

Finally, medical journalism is more than making abstracts, and reading proof, and making sprightly comments. It is cotemporaneous history of the rapid dawn of a new age of healing and preventive medicine.

American journalism, as a whole, is awake and alive, but still far back on the road. But to-day there is apparent a tremendous stir and movement, a consciousness of the great drift of events—of the drift of science, of the drift of journalism. This is the evolutionary current into which we must turn our journalistic barques if we ever sight the true port of the coming ages.

Society Notes.

KENTUCKY STATE MEDICAL SOCIETY.

Thirty-first Annual Session, held at Henderson, Ky., May 14, 15, and 16, 1890.

President Dr. J. A. Ouchterlony, of Louisville, in the chair, and Secretary Dr. Steele Bailey, of Stanford, at the desk.

THE Hon. John L. Dorsey delivered the address of welcome. Dr. A. Dixon read a report on the Progress in Surgery. The President read his address on the Early Practice of Medicine in Kentucky. Dr. G. Frank Lydston, of Chicago, made an address —Materialism *vs.* Sentiment in the Study of the Causes and Correction of Crime.

The following officers were elected: President, Dr. G. W. Beeler, of Clinton; Senior Vice-President, Dr. J. M. Poyntz, Madison; Junior Vice-President, Dr. A. Morgan Vance, Louisville; Permanent Secretary, Dr. Steele Bailey, Stanford; Assistant Secretary, Dr. J. Y. Oldham, Lexington; Treasurer, Dr. J. B. Kennard, Lancaster; Librarian, Dr. T. B. Greenley, West Point, Ky. The next place of meeting is Lexington, and Dr. David Barrows, of that city, Chairman of the Committee of Arrangements. Delegates were chosen to the National and the International Conventions.

At the banquet at the Barrett House toasts were responded to as follows: Kentucky State Medical Society, Dr. John A. Ouchterlony, Louisville; State Board of Health in Prevention of Disease, Dr. Pinkney Thompson, Pembroke; Art in Medicine, Dr. J. M. Matthews, Louisville; Philanthropy in Medicine, Dr. G. Frank Lydston, Chicago; The Ladies, Dr. L. S. McMurtry, Louisville; Medical Press, Dr. Dudley S. Reynolds, Louisville.

A ball was given at the Armory in honor of the doctors, and was very enjoyable. A profusion of Kentucky feminine loveliness added its charms to the occasion.

The address of the President of the Kentucky State Medical Society was made by Dr. J. A. Ouchterlony, of Louisville. He took for his subject the

PIONEER MEDICAL MEN AND TIMES IN KENTUCKY.

The noble adventurer who first (in 1747) plunged bravely into that pathless wilderness known as "the dark and bloody ground" was a medical man—Dr. Thomas Walker, who married a cousin of George Washington. The first practicing physician in Kentucky was Dr. George Hartt, at Harrodsburgh. The first surgical operation was done by Col. James Smith,

and was done on himself in the wilderness and with no one but a mulatto boy with him. Col. Smith was not a medical man. Mrs. Francis Coomes, the wife of Wm. Coomes, was the first lady physician. She was physician, surgeon, and obstetrician, and renowned in all. She was, according to tradition, the first to make bread or salt in the State. Among her posterity is a member of this society—Dr. M. F. Coomes, of Louisville. Dr. H. McMurtrie wrote (in 1819) the first history of Louisville, and discussed geological and philanthropic matters. He also has a descendant in the person of Dr. L. S. McMurtry, an ex-president of this society. The first medical book was published by Dr. Thomas W. Rubleland in 1810. The first medical society in the State was established in Louisville in 1819. A doctor's bill, dating from 1780, shows that Dr. Hartt charged Mr. Clews $240 for eight doses of calomel, and $240 for four blistering plasters. Among the early operations are two of excision of the pancreas in 1816. Biographical sketches were given of Dr. Frederick Ridgley, Dr. John Milton Harney, Dr. Walter Brashear, and Dr. Theobald.

Dr. Arch. Dixon, of Henderson, read a report on the Progress in Surgery. He made a comparison of the surgery of past years with that of to-day, and laid special emphasis on the use of antisepsis in the treatment of wounds. Laparotomy, intestinal, brain surgery, and the radical cure of hernia were carefully discussed.

GUNSHOT INJURY OF THE SPINE, WITH PARALYSIS; DEATH AFTER FOUR YEARS

was the subject by Dr. M. E. Alderson, of Ressellville. He presented the specimen showing the ball projecting into the spinal canal from the vertebræ where it was imbedded.

TWO CASES OF ECTOPIC GESTATION CURED BY ABDOMINAL SECTION

was the subject of a report by Dr. A. C. Bernays, of St. Louis. The first case reported was the first case of early operation for ectopic gestation successfully done in the State of Missouri. The examination of specimen showed an exquisite hæmato-salpinx due to a tubal pregnancy, the blood having escaped from the villi of the chorion at the point where the placenta was developing. The tube is distended so that it is two and a half inches in its largest diameter, and three and a half inches long. The surface of the tube is covered by shread-like adhesions, although in some places the peritoneal covering is seen in a normal condition. The muscular coat of the tube is much hypertrophied, averaging an eighth of an inch in thickness. The embryo was not found, but traces of it were seen in the shape of translucent gelatinous tissue, lying within the clot, which filled the tube. The second case was found in syncope after a ruptured ectopic pregnancy. This is a case where the patient's life was undoubtedly saved by prompt surgical interference. The pregnancy must have been between seven and nine weeks' duration. In many respects the case was an instructive one, and the doctor thinks it the first case of ruptured interstitial gestation which was saved by abdominal section.

BERKS COUNTY MEDICAL SOCIETY.

AT a stated meeting of the Medical Society of the County of Berks, held July 8, 1890, a report of the delegates to the State Medical Association, at Pittsburgh, was read, and received; also it was announced that the State Medical Association proposed meeting in Reading, June 7, 1891.

A Financial Committee was appointed, and the members present paid their first installment of money subscribed for the purpose of entertaining the society here next year.

Reading can now boast of having one of the finest railways or mountain roads in the State. Another will soon be in running order; the first being partly a gravity, the second an electric road. There is even now an electric road, leading several miles into the country. Steamboats carry passengers to several picnic grounds. We find here some of the finest views to be found anywhere in this or in any other State, bringing into view villages, towns, mountains, for twenty or more miles; besides, our large manufactories.

Socially, we think, there will be a treat in store for the society. What it will be, and how conducted, remains to be seen; we can only say, the County Society will make a strong effort to entertain the State Medical Association royally.

Reading has not had the pleasure of entertaining the State Medical Society since 1849, and, strange as it may seem, there is a coincidence in that the chairman of the State Society for 1891 should be chosen again from Lancaster county; this time, Dr. Craig, of Columbia. In 1849, Dr. Samuel Humes, of Lancaster, was president. Of the delegates of 1849 but three remain, Dr. Hiram Corson, Dr. J. Augustus Ehler, and Dr. J. H. Seltzer, now a lawyer of Philadelphia. Of the other members present at that session, Dr. Alfred Stille and Dr. Meredith Clymer are the only doctors that remain, or are known to have been present at that meeting. Possibly, some one can give us more information on that subject. That was the second meeting of the State Society of Pennsylvania.

F. W. FRANKHAUSER, M.D.

230 South Sixth street, Reading.

The Polyclinic.

PHILADELPHIA HOSPITAL.[1]

SERVICE OF DR J. B. WALKER.

SCURVY.

THE first patient I want to bring before you, came into the hospital four days ago, and as you see him to-day he is very much improved. He is pale, anæmic and sallow; his conjunctiva is yellow, and the inside of his lips is pale. His gums are swollen all along the borders of the teeth, and present a red line with some points of ulceration above and below. The upper gums show one hemorrhagic spot, which bleeds freely. His breath is very offensive and the gums are covered with fungus and hang over the crowns of the teeth, so that they are almost on a level with them. This is not so marked as it was yesterday, when I saw him for the first time. The condition is one of anæmia.

On exposing his limbs, we find that they are covered with little spots and larger areas like bruises. These spots are small petechiæ and resemble the eruption that is present in typhus fever. These petechiæ are small ecchymoses with absorption of the liquid part of the blood, while the coloring matter remains. Be-

[1] Reported by William B. Stewart, M.D.

side these petechial spots there are prominences along the front of the tibia of the left leg, and in the right the whole calf, to the popliteal space, is smooth, hard, rigid, and feels like a piece of wood with a cloth wrapped around it. You see a large node on the front of the left leg, but on the right not so much in the front as in the calf. The entire limb is swollen and puffy.

The feet are not swollen, and this shows us that the trouble is due to some local effusion and not obstruction of the vein. Taken with the anæmia, swollen and bleeding gums, the case is a typical one. The nodes on the front of the tibia are due to a subperiosteal effusion, while the enlarged calf of the other leg is due to an effusion into the inter-muscular septa. This is a typical case of scurvy.

Scurvy is a disease that is seldom met with outside of a large hospital. This patient is a German and works hard at his trade—a brickmaker. He has always been a healthy man. His diet was bread, milk, soup, and coffee, and *no* vegetables. Has no headache or vomiting ; pulse is regular ; does not have an alcoholic or specific history.

Here, then, is a patient who has been confined to a limited diet, without much variation, and no vegetables. A limited dietary, not varied, will induce scurvy under rare hygienic surroundings. In cases where a long voyage at sea is to be taken, to avoid this scourge of scurvy, a free supply of lemon and lime juice is given to the sailors daily. The absence of potatoes is an especial feature in scurvy. During the potato-famine in Ireland, a great many people died of scurvy, who would have lived if they had had a few vegetables.

An examination of the blood reveals a deficiency of coloring matter and red blood-cells. Dr. F. P. Henry reported two cases of scurvy, one year ago, in one of which the number of red blood-cells was diminished fifty-five per cent., and the hæmaglobin was reduced thirty per cent. Hence you see that the oxygenating power of the blood was grealy reduced. In an examination of the blood in the case before us, we find a reduction of the cells to thirty-nine per cent. of the normal, and in place of five million there are about one million cells. There is no excess of white cells, but rather a diminution. Henry found the white cells diminished in one of his cases. It is not a case of leucocythæmia, but a case where the corpuscular elements are reduced. The red are reduced in number and value, and this indicates a marked anæmia, which is verified by the marked pallor and sallowness of the face. There is another feature, and that is the increased fibrin forming material in the blood, which has been reported.

A prominent feature, in addition to the anæmia, is the hemorrhagic tendency. In other forms of anæmia you have this hemorrhagic tendency, but its general character distinguishes it from simple purpura.

Simple purpura presents a similar appearance to that in this man's leg, but the spots are larger as a rule, and there is not the general hemorrhagic tendency and condition of the gums. It is strange that this condition has confined itself to the gums surrounding the teeth, for if the tooth is lost you will find that the fungus is not on this part. It confines itself to the borders of the teeth, while the gums away from the line of the teeth are perfectly normal. Pressure on the border of the gums causes an escape of purulent fluid, like that expressed from abscess cavities. The gums are separated from the teeth. The condition of the breath is one that you find in many cases of anæmia, as also the alteration in the size, shape and value of the red cells of the blood, as is the case in pernicious anæmia.

Although scurvy is a pernicious anæmia in one sense, yet it is amenable to treatment in most cases. Where may these hemorrhages come from? They may come from the eyes, nose, stomach, kidneys, bowels, bladder, or may have a hemorrhagic pleurisy, or may take place in any of the serous membranes. Most, if not all cases of hemorrhagic pleurisy, should be classed as scurvy. In this case, the digestion is poor, and the bowels are constipated. When there are ulcers in the bowel, we may have dysentery and hemorrhage from the bowels. The ulcer will be long in healing, and will resemble the true, deep ulcers of dysentery. This man has none of these symptoms. The diagnosis of scurvy rests on the petechial eruption on the lower extremeties ; no fever and swelling of the gums, associated with anæmia, and there is no other disease for which it can be mistaken.

As a rule, in these cases, the temperature is below 99.4° F. The prognosis is always favorable, except in severe hemorrhage, or serous hemorrhages, which may be so great that the patient cannot rally.

Since the cause of scurvy is due to improper diet, the treatment is dietetic. We must build up the blood, and the idea is to give substances that will supply this want. Potatoes represent a prominent feature in diet, in addition, the administration of lemon and lime juice, with mineral acids. Exclude from the diet all forms of salt meats. Give fresh, succulent food, and fresh meat, and vary the diet as much as possible. Administer the lime and lemon juice continuously for the twenty-four hours, day after day—this constitutes the main line of treatment. Following this treatment, some form of iron is indicated. Blaud's ferruginous pills are preferable, in this case, to the other forms of iron. Some prefer the tr. ferri chloridi, on account of its acidity and styptic qualities, and, as a general rule, I think it is preferable. The value of this pill of carbonate of potassium and sulphate of iron, is that it is readily assimilated, and builds up the red cells. I think, also, that where there is marked hemorrhage, aromatic sulphuric acid is one of the most serviceable preparations, and I have seen cases of subcutaneous ecchymoses and inter muscular infiltration, disappear like magic under this treatment. Sometimes ulcers form on the legs, and exist for a long time, and are difficult to heal. Abscesses, with sanious pus, may form and discharge. In many of these cases an anæmic bruit is heard over the base of the heart, due to a temporary dilatation of the left ventricle, and any exertion in the upright position would frequently cause syncope.

[NOTE.—One week later this man was shown to the class very much improved. Treatment was continued.]

Improvement continued and patient made a good recovery.

TYPHOID COMPLICATED BY RHEUMATISM.

This patient is a driver, and has a good family history, and never was sick in his life before this time. He came to the hospital nineteen days ago, complaining of a pain in his side, due to a sprain from carrying a stove upstairs. Two days before he came in he felt weak and could not lift his arm. When he came in none of his joints were swollen, but he was weak ; had a swollen and tender abdomen, and a heavy pain and slightly delirious. On the eve of the second day there was an attack of epistaxis, bowels were distended, and the tongue approached the typhoid condition, with red tip and edges. There was pain in the

legs and arms on the third day after admission, and that evening there was marked swelling of the knee and right wrist, and a soft systolic bruit over the mitral area; epistaxis and tender abdomen.

The left arm and shoulder became involved. His morning temperature was 101.8° F., and his evening temperature 103.8°. Tenderness in the right iliac fossa. The temperature runs high in the evening and lower in the morning, and kept up all the time until the fourth day of admission, when it fell to 100°. On the nineteenth day the temperature reached the normal. By taking the temperature at the same hour morning and evening, it runs a very regular course; but by taking it every two hours in typhoid fever you will be surprised how irregular it is. It may vary two or three degrees in two hours without the use of antipyretics. Dr. Wilson had a record of a case of typhoid fever that ran below normal every day, owing to the fact that he did not take the temperature at a certain set hour each morning and evening.

I say, therefore, to look at this man's temperature chart, with the history just given, I think one is justified, in spite of the other symptoms that have arisen, in saying that typhoid fever had existed.

Rheumatism is a disease of slight fever, and is synonymous with rheumatic fever. Granted that these joints are involved, there would be a decided rise in the temperature, and with only one or two joints involved the temperature would hardly be affected. This man came into the house with a higher temperature than at any time since, and at that time there was no joint involvement. I think this shows that there was something else besides rheumatic poison at work in this man's system. True, this man had undergone extreme muscular exertion, and was in good condition for taking a chill and bringing on an attack of rheumatism, but, before the rheumatic poison had time to stir up any inflammation, he had a temperature one degree higher than at any time since. He had a high fever that has been associated with extreme muscular exertion; or retention of certain poisons in the system; or else he had typhoid fever.

There is no question in my mind that typhoid fever runs as variable a course as scarlet fever, and I think the German method of arriving at a diagnosis by exclusion is the best for us to pursue. I have no doubt but that this man had an attack of typhoid fever, which was complicated by an attack of rheumatism. His pulse varied from 90 to 120, rising with the fever, but mostly below 100 beats per minute. It is remarkable how slowly the pulse weakens in typhoid, and there are two points in the pulse beats that assist us in our diagnosis: First, a dicrotism from the early loss of vasomotor tone, due to the presence of typhoid poison in the blood, and second, the slowness of the pulse in relation to the fever. In typhus, pneumonia, and scarlet fever, see how very high the pulse runs, so that I can say typhoid fever, in this case, almost from the pulse alone. In typhoid, we look on a pulse of 120 as a grave point, and Stokes said this was an indication to stimulate. The presence of constipation is common, for many cases of typhoid run their course without movements from the bowels. Rheumatism rarely complicates typhoid, as it has done in this case.

The yellowish-white fur on the tongue, with the granular fungiform papillæ, can be seen, and the tongue looks like typhoid, but the same condition may be caused by sore throat. Rheumatism occurring in typhoid must be treated by local means, such as wrapping up the joints in flannel saturated with a solution of nitre, with the idea of reducing local heat and pain. In such a case salol would be the best remedy to start with, as it is applicable both to typhoid and rheumatism. It would not be wise to give salicylic acid, as it is too irritating and depressing in its action.

MORNING DIARRHŒA.

This man, to whom I now call your attention, presents a very peculiar temperature, flushed cheek and palor of the rest of the face. His tongue is coated, has diarrhœa, and a tenderness over the abdomen, most marked in the umbilical region. One year ago he was seized with an attack of diarrhœa that continued for one week. Last November, while husking corn on the wet ground, a slight attack of diarrhœa came on. He recovered from this and came to the city, and here his food disagreed with him and the diarrhœa returned. He would have to go to stool as often as eight times in one night, and blood was present in these stools. Since he has been resting he has improved somewhat. When he came in the blood that was passed was clotted and bright red in color. When he gets cold his abdomen swells. We have, then, in this case, a long continued case of diarrhœa.

Prof. Pepper, of the University of Pennsylvania, wrote of a diarrhœa that occurred once every twenty-four hours, and then consisted of a copious watery stool in the morning, and during the remainder of the day would have no return of it, and no annoyance until the next morning, when it would recur. The patient is frequently disturbed early in the morning and must go to stool at once. At the same time that this article appeared, a French writer called attention to this same condition of morning diarrhœa.

The patient before us was obliged to work, and was exposed to cold air when he had his attack, and, as a consequence, his diarrhœa became worse. What will cause it, I cannot say; but I consider such conditions as diarrhœas of indigestion, and they seem to persist, even in spite of all food, independent of quantity or quality. Every morning this patient had a copious liquid stool, in spite of milk diet; dry diet and the administration of no fluids at bedtime. All this made no difference, although the necessity for the avoidance of fluids at bedtime was insisted upon. He became pale, anæmic and his feet began to swell. I at last told him to eat anything he pleased, and it did not affect the diarrhœa.

I could readily put him on astringents and opiates and stop the discharge, but would it be wise to do so? I put him on a pill of nitrate of silver, gr. ½, and pulv. opium, gr. ⅙, at bedtime, and gave diet as usual, and he improved slightly. The pill was then given at 10 A.M., 4 P.M., and at bedtime, and he has improved so much that he is now nearly well. I am satisfied that my error in this case was, that this man had enteritis, while he suffered from internal hemorhoids at the same time. The treatment is modified on account of this fact of irritation in the rectum, and, to get rid of irritating matter, he is given an injection of a pint of hot starch water before he goes to stool. Probably most of his diarrhœa is due to irritation of the hemorrhoids. I think that it would be best to give sulphur in small doses, as it is the best laxative remedy in hemorrhoids. Wyeth prepares a tablet of sulphur, two or three of which can be taken three times a day and will answer better than the compound liquorice powder.

I think that in this case we must come to the astringent and sedative process early, and must use some silver preparation, oil of turpentine, or oil of erigeron. I am in favor of oil of turpentine, in pearls containing gtt. x, three times a day, which will have a tendency to heal all ulcers in the intestines. Diet must be regulated to suit each individual case, as necessity demands.

IS ALL DISEASE NEUROTIC?

WE have recently received three remarkable papers; remarkable in that each calls in question beliefs that are almost classical in their general acceptance by the profession, and each one urging the same variation in regard to a different disease.

In his address before the Pennsylvania State Medical Society, Dr. Mays continued the argument of his paper upon Consumption as a Neurosis. He objects to the bacillar theory in that it has not as yet advanced to any demonstrable extent in the way of curing phthisis. But surely it is no disgrace that a good foundation is laid, even if the house has not yet been built. The exceeding slowness with which mankind learns to use discoveries should not be forgotten. We possess arms and legs for years before we begin to learn what are their possibilities. Charles Lamb said that it probably required ages for mankind to learn that pig could be roasted without burning a house down. The remarkable properties of coca were discovered by Pizarro's Spaniards; but the drug was neglected for centuries until Koller took it up. If, then, little therapeutical advantage has as yet resulted from the discovery of the tubercle bacillus, this is neither a proof that this organism is unimportant nor that no such improved therapy can yet be deduced from that discovery.

His second objection is urged against the infectious nature of tuberculosis; and he quotes statistics from the Brompton reports, from Fuerbringer and Brehmer, to support his views. There are few theories which cannot be proved or disproved if a few statistics supplied from interested observers are to be accepted as final. We have not yet forgotten the anti-vaccination reports, which Körösi showed to have been deliberately falsified by an over-zealous opponent of vaccination. Statistics are of weight in proportion to the broadness of the field they cover, the accuracy with which they are made, the impartiality of the statistician. A few isolated cases are rarely of much value, unless illustrating some special phase. Sydenham's observations upon scarlatina would hardly be received to-day as giving a typical picture of that disease, good and honest observer as he was. It is quite in accordance with these remarks that Cornet's statistics lead to conclusions directly the opposite of those quoted by Mays. And, singularly enough, the decrease of phthisis in the town where Brehmer established his sanatorium is taken by Mays as a proof of non-contagion, while Flick cites it as evidence of the prevention of contagion by segregating consumptives from the healthy.

In regard to the transmission of phthisis from husband to wife, or *vice versa*, Mays quotes from several sources to show in how many cases no such transmission occurs. But in this also he goes too far. He simply gives evidence to show that the disease is not very contagious; that transmission does not necessarily occur. This we will all admit; even granting that there may be fallacies in his figures. But positive evidence will always outweigh negative; and a single case of proven infection goes farther than any number of negative reports. An instance occurred during our student days which is to the point. A farmer came to our preceptor for advice. He stated that consumption was unknown in his family, which had resided on the farm for several generations. He was a robust man, never ill, hard-working, but in easy circumstances that relieved him of the necessity of overwork or exposure. A year or two previously he had married a woman at that time phthisical; and before her death he himself gave evidence of the same disease. Now, here were all the elements of an infection; everything points to this explanation as the most likely to be true. To prove that this was *not* an infection would be far more difficult.

Dr. Mays deprecates the harsh measures adopted by those who accept the contagion theory; the separation of the patient from the family; the rigorous antiseptic measures, etc. There should be reason in all things; but we cannot look upon it as too much to ask that a consumptive should spit in a cup instead of a cloth; that the sputa should be destroyed; the patient sleep alone; and, after death, the premises be thoroughly rendered aseptic. These measures are designed to stay the progress of the principal cause of death all over the world. They are founded on a theory which, though imperfect, is the best at our disposal. Instead of sitting down and doing nothing, folding our hands until the microbe theory is so completely demonstrated that there remains none to doubt it, let us do the best we can with what light we have until we can do better. If consumption is a neurosis, the holders of that belief have not thereby added anything whatever to our therapeutics, nor have they given us a better means of checking the spread of the disease. The worst of all policies is a do-nothing one. A battle can better be won by vigorous action on a bad plan than timorous and inefficient following a good one.

Dr. Lydston gives us an ingenious paper, in which he attributes syphilis to a neurosis. Why not? Nevertheless, we will continue to believe that mercury will do more to cure it than electricity, massage, or any anti-neurotic regimen.

In the present issue Dr. Harkins contributes a paper in which he claims that choleraic affections are alike of neurotic origin. It will be difficult to find

credence for a theory which attributes epidemic cholera, cholera morbus, and cholera infantum to the same and a non-infectious cause. This would be to read the whole modern science of medicine backwards. Nor do we believe that the efficacy of counter-irritation over the vagus proves anything more than that this nerve is profoundly affected by some product generated in these diseases—and, if the remedy is equally efficient in all, it shows that the causal ptomaine is identical in all the choleras. But the one vastly important point in his communication is that blistering over the vagus in the neck produces effects in the cholera group which appear little short of marvelous. This is a matter easily verified, and if extended experience confirms Dr. Harkins' claims, we may thank him for a therapeutical suggestion, even if we do not accept his theory of its action. This is not the only case in which blisters have been found of unexpected utility, even in diseases of microbic origin. Boeck, by his process of "syphilization," accomplished results in the treatment of true syphilis which were afterwards shown to be as easily produced by ordinary blisters as by chancroidal ulcers. In tuberculosis, rheumatism, and pneumonia, the blister holds its place as the most valuable external application; while Dr. Harkins has also taught us the value of a blister over the liver in uncontrollable epistaxis.

Dr. Harkins can hardly be aware of the brilliant results won by the use of intestinal antiseptics in cholera infantum. From many sources we have the best reports from the sulpho-carbolates. At least twenty physicians have informed us of its great utility. In our own practice, this summer has thus far proved as successful as the two preceding—no case of intestinal flux in child or adult has failed to be relieved by this drug.

Annotations.

ANOTHER important discovery has been made in Germany. It is that powders may be taken nicely by twisting them up in paper and swallowing paper and all. To be sure, it is a special paper gotten from Japan, and called "Usego;" but there is not much likelihood that it is any better than tissue paper, which every physician has doubtless used for this purpose.

IN countries where red-tape rules, and official stupidity shelters itself under precedent, there is nothing more annoying to the official mind than the questions which arise from modern innovations, for which no precedent exists. In Austria the family of a man whose body had been cremated in Italy applied to the authorities for leave to keep his ashes in their house. [Why didn't they do it without asking permission?] The authorities were totally unprepared for such a conundrum, and a diligent search through the official rules and regulations showed that the disposal of cremated remains had never been considered. The question was referred to the Minister of the Interior, and he submitted it to the Supreme Sanitary Council of the Empire; and this body, by resolution, permitted the ashes to be kept in the house.

WHAT a comment it is upon the insight into hospital life obtained by the visiting physician, when we read in the evidence submitted to a committee (*Brit. Med. Jour.*) that "Sir Andrew Clark objected strongly to over-crowding, and when he visited the hospital a number of patients were wheeled out of his ward, and within half an hour after he was gone they were wheeled in again!"

If Sir Andrew was wise he would advocate a Board of Lady Managers, and such abuses would quickly cease.

WE recently gave an abstract of Dr. James Barr's paper describing the treatment of typhoid fever by continuous immersion in the bath. The greatest objection which then presented itself was the passage of the excreta into the bath. This, Dr. Barr informs us, through the *Provincial Medical Journal*, has been obviated by an apparatus by which the patient can be lifted completely out of the bath as easily as a window blind is drawn up. As long as the patient is conscious this will doubtless answer; but when the dejecta come away without notice, the continuous bath will become too filthy a method for general use.

AN Iowa girl was noticed to have a gradually increasing enlargement of the abdomen. The physician who was called in confirmed the parents' apprehensions by pronouncing the girl pregnant. Under the stress of this verdict, the girl's best young man was compelled to marry her. But the swelling has turned out to be a tumor; and an operation for its removal has resulted favorably. Now, the parties are debating whether the marriage should be accepted or annulled.

There is a pretty good rule for physicians in making such examinations. The one absolute sign of pregnancy is the beating of the fœtal heart. The examiner either hears this, or he don't; and in the latter case he must suspend judgment.

POST-EPILEPTIC AUTOMATISMS.

COLMAN, in a paper published in *The Lancet*, mentions a variety of unconscious automatic actions following epileptic attacks. The typical spasm has its three stages: First unconsciousness; convulsions, tonic and clonic; and second unconsciousness. Cases vary greatly in the degree to which each of these is manifested. The third stage may be nearly or quite absent; and sometimes in it the patient performs automatic acts of greater or less complexity. This may last some hours, and the patient awake, totally unconscious of what he has done. These automatisms may occur after very slight attacks of petit mal. The author divides them into the following groups:

1. Cases in which the patient merely talks. This resembles the speech of the somnambulist; it is not very coherent, and may be merely the repetition of some words.

2. Cases allied to somnambulism. The patient opens a window; goes into the street in her night dress; puts on clothes; brushes them; sweeps the floor; goes off by train, etc. In procursive epilepsy the patient springs to his feet and runs at full speed, avoiding obstacles.

3. Actions suggested by the feeling of malaise. He undresses, or otherwise indicates his instinctive impulse to go to bed.

4. Kleptomania. It is not uncommon for such patients to pocket any small objects within reach.

There is usually no choice; the nearest objects being taken, though others of greater value are left.

5. Violent acts. These are commonly seen in asylums. Many murderous assaults have been committed in this state. In one case a youth repeatedly tried to mutilate his own genitals, and once a brother's.

6. Micturition. Trousseau's famous case is mentioned, of the judge who left the court room and urinated in a corner of the council room. A young girl seized with petit mal micturated in a crowded assembly.

From these cases he draws the conclusion that it is not necessary that the fit shall be severe to produce such automatic acts. On the other hand, it does not follow that all such aberrant impulses in an epileptic are necessarily automatic. From isolation, mental deterioration, etc., these patients often become morally degenerate, suspicious and irritable.

UNGRATEFUL JERSEY.

OF all the States in the Union, New Jersey profits most by the annual exodus from the cities caused by the summer heats. From the classic precincts of the Navesink to where Cape May is dimly visible through the clouds of mosquitoes, her shores are lined with hostelries, into which are poured millions of dollars annually by the citizens of other States. Others have one or even several summer resorts, but no other State is given over so entirely to the business of caring for summer visitors as is Jersey. For this popularity, among other factors, we may assuredly claim a share of credit to the medical profession. To many persons, in making up their minds where to go for the summer, the comfort of having the family physician within easy reach is enough to decide the choice. This was recognized by the old Camden and Atlantic Railroad, and their liberal distribution of season passes among physicians was probably the principal reason that Atlantic City so far outstripped her rivals in the race for popularity. People liked to go with their doctors; the latter preferred to send their patients where they could be reached easily and with least expense. This gave Atlantic City an advantage over other places just as near, just as healthy, as desirable in every way. But now the work is done, and Atlantic City has got such a start that competition will never catch up to her; and the physicians get no more passes.

And although the Jersey coast doctors reap a golden harvest every summer, which enables them to amuse themselves the rest of the year, they are not satisfied with abundance, but want all. So they have had a foolish little bill passed through the Legislature which compels any city physician who wishes to accompany his patients for the summer, to first go to Trenton, pass an examination before a board of physicians who don't want him in the State, and pay a fee. The result will be that many New York and Philadelphia physicians will turn their steps towards the summer retreats in their own States. They will very soon begin to wonder why they ever left them for Jersey sands; and the result will be a diversion of the stream of popular travel to the mountain resorts. Not only will this apply to those directly interested, but to many others; for it is not the least among the attractions of any resort to know that the celebrated Dr. Smith, or the great surgeon, Prof. Brown, goes there. People are quick to jump at the conclusion that there is something specially valuable about a place which is endorsed by such high authority. We have already expressed our opinion that the sea-shore receives far more attention than it deserves, and think a diversion in favor of the hills will be greatly to the public benefit; but as far as New Jersey is concerned, she is killing the goose that laid the golden egg.

Book Reviews.

To the third and four numbers of Volume XLVI of the "German Archives of Clinical Medicine," Dr. Fritz Moritz, of Munich, contributes "On the Cupric Oxide Reducible Substances of the Urine under Physiological and Pathological Conditions." The presence of grape sugar in normal urine, and the distinction between its normal appearance and as a product of disease, are made the subject of many experiments, and promised further investigation. The principal point made is that the usual methods of investigation resulting in the finding of sugar (Trommer's and Fehling's tests, etc.), cannot in every case be considered as conclusive.

Prof. Fürtner, of Heidelberg, "On the Body-Weight in Psychoses," accompanies his contribution with charts showing the fluctuations, which are especially striking in periodical mania, and establish a definite relation between the loss and the mental condition, and the ultimate recovery of the normal weight, with recovery from the disease.

Prof. Von Ziemssen, "On Comparison of the Pulse on the Two Sides, and its Significance in Disease of the Arch of the Aorta," gives tracings, comparing the two sides, and ascribes the results to stenosis from pressure on the branches of the aorta, resulting from aneurism, or mediastinal tumors.

Prof. M. J. Rossbach, of Jena, in "Contributions to the Knowledge of the Movements of the Stomach and Duodenum," and in a second article, "Observations on Movements of the Bowels in Man," draws the conclusions that in the early morning movements are absent; that they occur in fifteen minutes after introduction of food and alternate with pauses; that of ordinary articles of diet, no appreciable difference of intensity can be detected, except for coffee, which excites strong peristaltic movements; that under all circumstances the peristaltic waves are constantly differing in intensity, and often interrupted with complete pauses; that slight cold (baring the walls to the atmosphere) excites; decided cold (sprinkling with cold water) only slightly affects; that decided sensations of hunger produce lively motions; that emotional impressions, as fright, result in checking for ten or fifteen minutes.

Dr. V. Maximovitsch, of Warsaw, and Dr. Rider, of Munich, "Observations on Variations of Blood-Pressure Resulting from Muscular Exertion and Ingestion of Liquids," conclude:

1. That three to five minutes after exercise begins the blood pressure is increased and the heart accelerated, and that the normal is regained with twenty to thirty minutes rest. In certain pathological conditions, no increase, and even diminution of pressure occurs, accompanied usually with urgent dyspnœa.

2. Ingestion of liquids increases pressure and pulse rate. Beer most, then in their order, wine, coffee, tea, cocoa, and water.

3. Muscular exertion, combined with ingestion of fluids, result in the greatest rise of pressure and pulse rate, and here, too, individual peculiarities and character of liquids modify the results.

4. Certain drugs affect pressure. Inhalation of amyl nitrite causes decided rise of blood-pressure.

Prof. Oswald Verordt, of Heidelberg, "On Tubercular Peritonitis and its Treatment." In view of dif-

ficulties underlying the diagnosis of tuberculous from simpler forms of subacute or chronic peritonitis, and in consideration of the uselessness of tapping and the marked beneficial results of section in some of these instances, he recommends the early resort to laparotomy, after failure of rest and ordinary medical means, and before the onset of exhaustion.

Prof. G. A. Sacharjin, of Moscow, "Syphilis of the Heart," directs attention to diagnostic means, and recommends specific treatment.

Dr. M. V. Frey, of Leipzig, contributes, "Physiological Remarks on Hypertrophy and Dilatation of the Heart." Samuel Wolfe, M.D.

Leçons sur les Maladies du Larynx. Par le Dr. E. J. Moure, Professeur libre de Laryngologie, Otologie et Rhinologie; Directeur et fondateur de la *Revue de Laryngologie*, etc. Recueillies et Rédigées par le Dr. M. Natier, ancien chef de clinique du docteur E. J. Moure, et revues par l'anteur. Avec des figures en noir dan sle texte. Paris: Octave Doin, éditeur, 8 Place de l'Odeon, 1890. 4to., pp. 599.

French physicians have mainly relied upon foreign writers for works upon laryngology during the last fifteen years. In this volume the author records his experience of twelve years' special practice, paying particular attention to the clinical features. The wants of the general practitioner are held in view, in the presentation of typical laryngeal lesions, specially useful instruments, and formulas which have given satisfactory results. Each chapter is preceded by a summary of its contents; greatly facilitating the search of the reader who has a case of which he wishes information. Certain subjects are dilated upon by the author; such as acute œdematous laryngitis, atrophic coryza, dry pharyngitis preceding dry laryngitis, the different modes of treating tubercular laryngitis, the paralyses and contractures of the laryngeal muscles, the existence of a cortical center, etc. The anatomical description of the larynx found in all classical works on anatomy is omitted, except so far as it is necessary to elucidate the paralytic affections. Laryngeal hemorrhages are relegated to the disorders of circulation, instead of describing a hemorrhagic laryngitis. Vocal troubles are recognized to be consecutive to catarrh, or due to muscular disorders. Laryngeal lupus is a rare form of laryngeal tuberculosis. The arrangement is rather clinical than anatomical. The epidemic of influenza occasioned the addition of a chapter on that affection to the work. The illustrations are few in number and poor in execution, as compared with those in recent American works.

Practical Sanitary and Economic Cooking; adapted to persons of moderate and small means. By Mrs. Mary Hinman Abel. The Lamb Prize Essay. Published by the American Public Health Association, 1890. 12mo., cloth, pp. 182.

A plain and sensible little book, dealing with the question of diet as it presents itself to persons of small means and average education in the culinary art. It is a good book to place in the hands of those who would find the ordinary cook-book, with its well-stocked larder and fancy grocer's stores, almost useless.

Pamphlets.

A Case of Hæmatoma of the Ovary following Chronic Catarrhal Salpingitis; with Operation and Recovery. By R. Harvey Reed, M.D. Reprint from *Cincinnati Lancet-Clinic*.

Gunshot Wounds of the Abdomen. By Aug. Schachner, M.D., of Louisville. Reprint from *Annals of Surgery*.

The Medical Digest.

Basch reports unfavorably on hydracetin, finding it unreliable and toxic.

A saturated solution of camphor in olive oil will dissolve 6 per cent. of iodoform.

Red bilberry (Vaccinium Vitis Idæa, Linn.) is a Russian remedy for chronic rheumatism.

Iodism, according to Grœnow, is sometimes manifested by a rapidly supervening œdema of the glottis.

Methylene blue is said to be an efficient analgesic, when given in doses of one to four grains. It can be used hypodermically if pure.

Porcher speaks highly of phenacetine as a hypnotic. Seven to ten grains is the dose, given at bedtime in a little water.—*Med. Record.*

Chronic articular rheumatism is one of the *opprobria medici;* but Hochhalt confirms Korda's recommendation of pilocarpine as of decided benefit.

Naphthol can be given internally by dissolving it in oil of sweet almonds, one part to ten, by the aid of heat. The oil can then be made into an emulsion.

Seaman (*Med. Record*) has invented an apparatus by which a double stethoscope is united to a percussion hammer, so that the stroke of the latter is conveyed directly to the ear.

Kendal Franks (*Brit. Med. Jour.*) describes a renal calculus removed by operation, which was found to have an ordinary sewing needle as a nucleus. The needle was supposed to have been swallowed seventeen years previously.

Muller states that in persons suffering with cancer the excretion of nitrogen far exceeded the amount ingested; the excess being derived from the albuminoids of the body. The chlorides were notably diminished.—*Med. Record.*

Handfield Jones mentions four cases in which castor oil produced unexpectedly violent effects. The English oil is very inferior to the American; the former often containing irritant elements, which the expression process used here leaves behind.

Methacetin, recommended by Meinert as a good antithermic for children, is also endorsed by Seidler. Five to ten grains is the dose. Free sweating attends its action. The temperature begins to fall in from fifteen to thirty minutes, and reaches its maximum in three hours.

Enphorbia pilulifera has been given by Workman (*Ther. Gazette*) in twenty-seven cases, with these results:

In thirteen cases of hay asthma, prompt relief ensued in nine; partial in one, and none in three.

In nine cases of coryza, good results were obtained in six.

In five cases of asthma, marked relief was experienced in one only.

The fluid extract was given in doses of 30 to 60 minims every four hours.

BELL (*Lancet*) suggests that in rheumatism the salicine compounds act as antiseptics, destroying or paralyzing the pathogenic virus, and thus enabling the kidneys to more efficiently perform their functions. Much the same effect is produced by frequent rectal enemata, cutting off the supply of toxic matter absorbed from the bowels.

CUNNINGHAM (*Indian Medical Gazette*) reports that three distinct species of comma-bacilli are found in cholera stools. These related to the three hospitals from which his material was derived. This suggests a means for reconciling the conflicting statements in regard to various points in the life-history of the comma-bacillus.

EMPYEMA is treated by Fernet by injections of naphthol, in diluted alcohol; naphthol, 5 parts; alcohol, 33, and water, 62. Four or five drachms of this are injected after the pus has been evacuated. This is repeated five times, at intervals of three days. This method is applicable to cases unsuitable for operation, infectious and circumscribed cases.

MULTIPLE VESICAL CALCULI.—Cunningham describes in the *British Medical Journal* a case in which twenty-three calculi were removed from the bladder, and twelve more from the urethra of a patient, in one day. Lateral lithotomy was performed, the incision being made to include two fistulas. The total weight of the calculi was 460 grains. The patient recovered.

CASCARA AMARGA is recommended by Haines (*Therap. Gazette.*) as almost specific in the ulcerations of tertiary syphilis. The drug was given internally to his case, with iodine; but as the patient had failed to improve upon iodine alone, and all improvement stopped when the supply of cascara ran out, and when a new supply was procured the patient resumed her progress toward health, Dr. Haines is warranted in attributing the cure to the cascara.

ANTHRAX.—Casson describes three cases of anthrax (*Brit. Med. Jour.*) occurring in Persia, in which he used with success hypodermic injections of sublimate. In the first case, two drachms of a 1–1000 solution were injected into the brawny tissue at four different points, and the same solution applied on a compress. The following day the patient's condition was much improved, and half the quantity was injected. Two days later, one more drachm was injected; and the cure was complete in ten days. The other cases were very similar.

HOFFNER says that bromide of ethyl should be administered by pouring two and one-half to four drachms over a sponge, in a tightly fitting mask covering the nose and mouth. In twenty to thirty seconds the anesthesia is sufficient to allow of short operations, and when the mask is removed, consciousness returns almost immediately. This is the anesthetic for consultation examinations; especially as it abolishes pain while consciousness remains; but as it does not produce muscular relaxation, it is not suitable for hernias or luxations.—*Provincial Med. Jour.*

VOLUNTARY BORBORYGMUS.—An interesting example of borborygmus, in which the patient was able to produce the intestinal gurgling at will, is described by Dr. B. W. Richardson, in the *Asclepiad* for June, and commenting on it the writer remarks that cases of this kind are the nearest to any of hysteria in the male subject, being sometimes attended by indication of globus hystericus, as in the patient under consideration. Such patients learn by a kind of abnormal instinct how to call into play symptoms of a peculiar order, like this induced borborygmus, the *modus operandi* being muscular pressure on the descending colon at a time when it was distended with gas.

—*Med. Press.*

SALOL IN CHOLERA.—The *Indian Medical Gazette* for May contains two reports. Hehir treated seventy-seven cases with sublimate, with thirty-nine deaths. Eleven cases were treated with salol, and all recovered. The drug was given in doses of 10 grains every two hours, with 15 minims spirits chloroform. No immediate change took place, the symptoms gradually abating. Two marked effects were the absence of uræmic symptoms and the short convalescence. These cases occurred at the close of the epidemic, when the tendency to recover is greatest. Stevenson reports four cases treated by salol, all of which died; two with suppression of urine.

INVERSION OF THE UTERUS.—1. Traction upon the cord does not produce inversion of the uterus; it facilitates it in cases where inversion is inevitable.

2. Inversion of the uterus is preceded by paresis of some portion of the uterine wall.

3. That paresis most frequently results from excessive stretching or laceration of muscular fiber, and is not governed by the location of placental attachment.

4. Excessive thinning of the lower uterine segment favors inversion of the uterus by temporarily impairing or destroying the power of muscular tissue.

5. When paralysis of the lower uterine segment exists, either spontaneous expulsion or expression of the placenta will be more apt to produce inversion than traction upon the cord.

—McCoy, *Ind. Med. Journ.*

DIET FOR OBESITY.—July and August.

Meat.—Beef, mutton, grass-lamb, buck-venison, veal.

Game.—Fowls, chickens, pullets, turkey-poults, rabbits, leverets, plover, wheatears, wild chickens, pigeons, wood-pigeons, grouse.

Fish.—Dace, dory, cod, carp, brill, barbel, crabs, crayfish, flounders, haddock, ling, mackerel, lobsters, mullet, thornback, plaice, pike, soles, tench, gurnet, perch, dabs, prawns, whitings, trout.

Vegetables.—Kidney, windsor and scarlet beans; asparagus, cresses, vegetable marrow, artichokes, celery, endive, chervil, cabbage, cauliflowers, cucumbers, shallots, leeks, sea kale, lettuces, mushrooms, salsify, spinach, sorrel, radishes, turnips, salad, peas, tomatoes, onions, sprouts.

Fruits.—Apples, oranges, pineapples, currants, cherries, damsons, gooseberries, strawberries, raspberries, plums, peaches, nectarines, filberts.

—From Davies' *Food for the Fat.*

AT the Royal Academy of Medicine in Ireland, Dr. Conolly Norman read a paper on acute confusional insanity. He pointed out that this form of psychoneurosis occupied an intermediate place between acute mania and the acute dementia of the older classificatory schemes, and contained a very large number of cases. It is characterized by engagement of consciousness in the form of dreamlike confusion, together with hallucinatory disturbance. It is interesting to others than specialists, because it is the form of mental disturbance which is most often associated with diseases not primarily affecting the nervous sys-

tem. Puerperal, post febrile, rheumatic, phthisical, and other varieties of insanity depending on general diseases, commonly take this form. Dr. Norman dwelt upon its frequency in alcoholic cases, and pointed out that the peculiar mental disturbance described by Korsakow, Ross, and Wiglesworth, as accompanying alcoholic neuritis, was a variety of acute confusional insanity. He detailed a number of illustrative cases, including several alcoholic ones, and defended the differentiation of this affection on etiological and prognostic grounds, as well as because the distinction tended to more accurate clinical description.—*Med. Press.*

THE TREATMENT OF CYSTITIS IN WOMEN.[1] (By Thomas More Madden, M.D., F.R.C.S.Ed.)—Of all the diseases which come before us in gynæcological practice, there is none more frequently met with, more distressing in its effects, or more intractable to the means generally relied on for its relief than cystitis in women. I therefore desire to bring under the notice of the International Medical Congress a method of treatment which I have found, by clinical experience, to be generally successful in the rapid curative treatment of this condition. The measures most commonly employed in such cases are merely palliative, and may relieve, but *per se* can never cure, well-established cystitis in women. Nor am I aware of any method by which that can be accomplished save by giving the bladder absolute physiological rest. For this purpose, Dr. Emmet's operation—*i.e.*, the establishment of an artificial vesico-vaginal fistula—may be successfully employed in some instances; but the practical objections to it are so great and obvious that, for several years past, I have abandoned this procedure in favor of another, which I have found more generally effectual, and quite free from the disadvantages of the operation referred to. The plan, which I have now employed in a very large number of cases of cystitis in the gynæcological wards of the Mater Misericordiæ Hospital, Dublin, consists, firstly, in the full dilatation of the urethral canal with the instrument exhibited, so as to paralyze the contractility of the sphincter vesicæ and canal, and thus produce a temporary incontinence of urine; and, secondly, in the direct application, through the same instrument, of glycerine of carbolic acid to the diseased endo-vesical mucous membrane. I may add that any pain thus caused may be prevented by the previous topical application of a solution of cocaine, and that the procedure recommended seldom requires to be repeated more than once or twice, at intervals of a week or ten days; and, combined with the internal use of boric acid, rarely fails to effect a rapid cure in any ordinary case of female cystitis.

GLEANINGS FROM THE MEDICAL WORLD.—

Antifebrin has been noticed to cause a mild cystitis. —G. T. Converse.

When a truss-pad irritates in old hernias, apply the faradic brush to the skin, give arsenic, quinine, and strychnine, and apply an air cushion or soft rubber pad to retain the hernia. —T. W. Forshee.

In an extreme case of inflamed breast, I used a fluid extract of phytolacca (green root), making a strong lanoline ointment and giving full doses internally. Complete success. Forty-eight hours decided the case. —L. H. Kitchell.

For warts, remove the outer scarf and apply a saturated solution of ammonium chloride several times a day, until the wart disappears.

For seat-worms, use the remedies in suppositories with cocoa butter.

For hypertrophy of the heart, use tinct. kalmia latif. —C. M. Brucker.

For superficial ulcers or inflamed surfaces, including burns, [crude] coal-oil is antiseptic, sedative, and generally healing. —G. T. Dunlap.

Sixteen cases of small pox with three deaths. Jaborandi was employed to prevent "striking in." —G. S. S.

Phytolacca has proved a specific for diphtheria; 32 out of 34 cases being treated successfully with it. The fluid extract was given in doses of 2 to 6 drops every two hours, and a gargle used every hour, of 50 drops in a glass of water. —S. A. Gifford.

A popular and often fatal error is the idea that children's bowels should always be very loose during dentition. Children never have diarrhœa from cutting teeth in winter. For a child in its second summer, saturate it with hot water; when it wakes, give calomel, gr. ij, ipecac, gr. ⅓, and soda bicarb., gr. iv, every hour. Have bowels moved in six hours; after which, if the stools are watery, give ⅓ to 1 drop of fl. ext. belladonna every hour or two; also bismuth tannate, gr. v, pulv. dover, gr. j, lactated pepsin, gr. j, as needed. If the dejections are offensive, creasote with a little chloroform water. Quinine is often needed for fever, and for dry skin a warm bath and jaborandi. —S. A. Butterfield.

SPANISH TRANSLATIONS.

By DR. WM. F. HUTCHINSON.

COCAINE IN SHORT OPERATIONS.—At the children's clinic of Prof. Del Rio, at Santiago, the following record was made.

"A boy of thirteen years was admitted for amputation of the right index finger, destroyed by a circular saw. So great was his fear of anesthesia, by reason of suffering during a previous experience, that it was decided to try cocaine. Following the line of the projected incision, five dermic injections of a few drops each were made, in all six centigrammes of a six per cent. solution.

"Two minutes later the cutting began, and was absolutely painless, including trimming off torn flesh and section of bone. After hemorrhage, which was but slight, was controlled, five stitches were taken without suffering.

"The time occupied by the operation was from eight to ten minutes, during all of which no pain was felt by the patient, nor any sensation except contact of the bandage, and this was attributed to a neighboring finger.

"It is Del Rio's opinion that very much is to be expected from cocaine in short operations, and that in those cases where its use was a failure, it was on account of the faulty way in which the injections were made. They should always be made into the skin proper, never subcutaneously.

"The amount used in this case gave rise to no accident, and the wound healed by first intention."

TREATMENT OF GONORRHŒA.—The strongest indications for treatment are, of course, twofold:

1. Destroy gonococci.
2. Restore to normal equilibrium the various disturbances induced by them.

The prompt and permanent removal of destructive conjunctivitis venerealis in the new-born child con-

[1] From advanced proofs.

clusively shows that gonorrhœa, under certain conditions, may be quickly and radically cured.

The internal remedies are chiefly copaiba, santal, and terebe, and certain mineral waters.

For urethritis iodoform pencils are useful. Dilatation is needful only when marked tenesmus is present.

Urethral ulcers are best touched with nitric acid or with the thermo-cautery, as lunar caustic is prone to lead to atresia.

For vesical catarrh it is sometimes needful to wash out the bladder; the best materials are corrosive sublimate, 1–8000 to 1–6000, by means of Küster's glass funnel; acetate of lead, 1–1000 to 1–500; nitrate of silver, 1–2000 to 1–500, and in bad cases even stronger. If the ureters and pelvis of kidney be seriously involved, we may think of colpocystotomy.

Bartholinitis is often difficult to cure; the entrance to the follicle cannot be approached. Local cleanliness greatly aids matters. Small Bartholinian abscesses should be freely opened with full antiseptic precautions. By far the best plan is to extirpate altogether by means of Paquelin's cautery.

Sänger says: "I have often seen severe pelvi-peritonitis as a result of neglected Bartholinian abscess."

Both for chronic Bartholinian inflammation and for fistula of these glands complete extirpation is absolutely needful.

For condylomata, if small, caustic may be used; for the larger growths scissors and the thermo-cautery answer well. Intertrigo and erosions promptly disappear by observing strict cleanliness, and by the removal of the corrosive discharge.

Pruritus vulvæ is sometimes rather intractable. Irrigations with solution of oak bark; painting with glycerole of tannin, also, weak preparations of boric or of carbolic vaseline; hot sitz baths, and the free use of soft soap are to be commended, also, ichthyol and liquor carbonis detergens.

Oppenheimer has made many careful experiments on the gonococcus with the various poisons which would prove the least inimical to the living tissues. He finds that corrosive sublimate and creasote kill the coccus most quickly and certainly. Sänger prefers these, therefore; and the next best, but a long way off the perchloride of mercury in value, is the chloride of zinc.

For acute vulvitis and colpitis he uses a solution of from 1–2000 to 1–500, according to circumstances.

For the cervix and the urethra Angerer's sublimate pencils are useful. These are of the strength of 1–1000. They are placed in the respective canals, and, being retained by means of absorbent cotton pads, are allowed to melt *in situ*.

For a very bad case the following treatment is excellent; Fill the vagina with tampons of glycerole of tannin, carefully packed; next day remove the tampons, and with it the superficial layers of epithelium will come away; now douche well with soapy water, then with plain water; afterwards syringe with the sublimate till no flakes come away; now swab the whole carefully with the sublimate solution on absorbent cotton mounted on forceps or a stick; dry out well, and again pack the vagina quite full with iodoform gauze, or, still better, with glycerole of iodoform.

In cases where there are "adenoid" neoplasms, it is well to pencil over the whole vagina with tincture of iodine finally.

Endometritis Gonorrhoica.—The leading indication in this disease is to keep the cervix thoroughly patulous. This is needful to get rid of the tough, ropy mucus which often blocks the canal, and is an element of peril as well of pain. For, acting like a dam, it keeps back clots and various discharges. It does not do to depend upon one single dilatation. The ostia must be kept dilated. Sänger keeps the cervix open by means of a glass rod. Sometimes he prefers to plug the cervical canal by means of iodoform gauze, having started the dilatation by means of a fine laminaria tent dipped in iodized phenol. Though he views with disapprobation the American plan of curetting the endometrium, condemning it, in point of fact, as leading to endometritis acuta, metritis, salpingitis, and pelvic-perimetritis, Sänger does not hesitate to irrigate the endometrium. Using a double canula he washes out the uterus with solutions of sublimate, sometimes adding to it zinc chloride, creasote, carbolic acid, or creoline. He also recommends swabbing out the interior *à la* Lombe Atthill, with 10 per cent. of chloride of zinc or a mixture of tr. iodine 1.5, and zinc chloride 50 per cent. The use of silver nitrate he has abandoned because of its tendency to lead to atresia cervicis. To treat these cases successfully they must be put to bed from four to eight weeks. It is sometimes well to explain to the friends that exudation often extends to the uterus, to the ureters, to the bladder, but more especially into the rectum. Occasionally a perforation takes place into the rectum, and under these circumstances the case is mistaken for one in which purely intestinal disease has supervened to complicate matters. Next to rest Sänger speaks highly of ice bladder to the abdomen. Opium given internally, combined with a very rigid diet. Hot vaginal douches are lauded, but with certain restrictions. They are never to be used in the acute or subacute stages of pelvic inflammations, because they increase the tendency to pyogenic change. Of course, massage is contra-indicated at this period. Saline and mud baths act wonderfully in the chronic stages. The best are Franzenbad, Elster, and Kreuznach. Pyosalpinx occasionally bursts into the peritoneal cavity, but this is rare; more frequently the pus finds its way into the bladder, into the vagina, or into the rectum. If we suspect a rupture into the peritoneal cavity, of course the right treatment is to open the abdominal cavity and wash out well. Sänger appears to be very shy of removing the appendage, he hedges it 'round with so many restrictions; finally saying that it should be done only in quite hopeless cases, more particularly if they be associated with tubercle. A contemplation of the foregoing facts must convince us that we are dealing here with a problem of vast social importance which cannot be safely ignored, and will not be conveniently shelved.

Purulent Ophthalmia of the New-born.—It is to be remembered that conjunctivitis purulenta may be purely catarrhal. But in intensity it is a very different disease from the alarming venereal form so terribly destructive to the vision that every pre-parturient woman should be ordered germicide douches on the merest chance of the presence of active diplococci. If one or more preceding children have had severe purulent ophthalmia, it is a highly confirmatory element in di gnosis.

Prophylaxis.—Sänger attaches great importance to sublimate injections about 1–1000. These can be persevered in for one month without salivation, not without peril after delivery. The power of infecting in men is protracted far beyond the limit that might seem probable. Thus Oberländer, quoted by Sänger, observes that gonorrhœal virus will remain active during not less than fifteen years, in cases where the membranous portion of the urethra has been affected, and the ducts of the seminal glands are involved.

DR. H. S. STETTLER is at Asbury Park.

DR. N. DAVIS, of Camden, has a cottage at Ocean City.

DR. J. H. GROVE and wife are at the Wiscasset, Pocono.

PROF. WOODBURY is at the Glen Summit for the summer.

DR. T. H. ANDREWS has visited Mayor Fitler at Elberon.

TWO English colliers traded wives. Better endure the ills, etc.

DR. MILTON J. ROSENAU has gone on a trip West to visit relatives.

Dr. GOODSON was killed at Bodie, Cal., by the explosion of a steam boiler.

DR. J. P. PATTERSON, of 1305 North Broad street, had his horse stolen last week.

DR. R. S. WHARTON is resting at Atlantic City from his hard work at Johnstown.

DR. LEVIS has been quite ill at his residence at Kennett Square, but is now recovered.

DR. E. G. O'MALLEY, of Wilkesbarre, was thrown from a horse and killed at Aspen, Colorado.

RICHMOND, Va., has—with a population of 100,000—no city hospital, and no public city dispensary.

DR. EUGENE E. FALKNER, of Bridgeport, Conn., was killed by a train while crossing a track in his carriage.

DR. JOHN E. ENSELL attempted suicide in New York last week by shooting himself. The wounds proved fatal.

THE Woman's Medical College, of New York, expects to move into a new and commodious building the coming fall.

DR. JOHN H. MUSSER, of Fortieth and Locust streets, has left for Europe to attend the International Congress.

DR. J. C. HUTCHINSON (formerly of Philadelphia, now of Wild by-the Sea) is building a handsome cottage at that place.

PASSENGERS arriving in New York from Havana state that the yellow fever is raging there; fifty cases a day are reported.

DR. LEONARD R. ROECKER, of Walnut street, is a guest of Judge Gordon, at the latter's beautiful cottage at Spring Lake.

THE July number of the *Medical Mirror* contains a very good portrait of Dr. E. A. Wood, of Pittsburgh, "the Lion of Peru."

DR. CHRISTIAN H. F. PETERS, the astronomer, was found dead in his bed at Clinton, New York, on Saturday morning last.

B. C. MORTON, JR., son of a physician of Guyton, Georgia, last week shot and killed two brothers in a quarrel over a mule trade.

LEPROSY has affected five thousand of the forty thousand natives of New Caledonia, and is now beginning to attack Europeans.

PARIS gossips declare that one of the regular physicians who was most conspicuous in ridiculing Dr. Brown-Séquard's "elixir" has just been cured of paralysis by its administration, and is now as zealous an advocate of Séquard as he was previously a scoffer.

DR. STEPHEN E. KETCHUM, of the resident staff of the Philadelphia Hospital, will take a trip to Boston, by water, for a vacation.

DR. JOSEPH TAYLOR, of Kennett Square, a brother of the late Dr. Franklin Taylor, died last week at the Cataract House, Atlantic City.

AN epidemic of typhoid fever occurred recently at Waterbury, Conn. Forty persons were infected from a dairy farm in the neighborhood.

DR. REBECCA FLEISHER sailed for Europe on the 5th inst. for the purpose of visiting her brother, Mr. Simon Fleisher, who went abroad.

RED BANK'S attractions attracted to its banks last week Drs. Jas. Radcliffe, of Washington, J. R. Jester and J. Kingsbury, of Philadelphia.

THE thirteen-year-old son of Dr. Freeman, of Hellertown, Pa., was killed, and five others were injured, by a wind-storm at that place last week.

DR. OTTMAR ANGERER has been promoted to Ordinary Professor of Surgery at Munich, and Interim Lecturer and Operator in Clinical Surgery.

THE mid-summer meeting of the Luzerne County Medical Society will be held at Glen Summit Hotel, Glen Summit, Pa., on Wednesday, August 6, 1890.

THE *Med. Press* says that a man was found near Eastbourne, with four nails driven three inches deep into his head. They were removed, with difficulty.

DR. ALEX. P. LONG is cruising about the Chesapeake Bay in his yacht, Hustler, with headquarters at Oxford, Md. He returns to Philadelphia September 1.

AMONG the many good things for which Holmes is responsible there are none more felicitous than when he describes the doctors as "the soft-handed sons of toil."

DR. F. N. OGDEN, Past Assistant Surgeon of the U. S. Navy, and now stationed at the League Island Naval Station, is sojourning with his bride at Atlantic City.

DR. PAUL GIBIER, of the Pasteur Institute, sailed last Saturday for Europe. He will visit M. Pasteur, in Paris, and then attend the International Medical Congress.

SOME railroad companies hire doctors by contract and get a large amount of work from them, including some expert testimony, for a very small salary paid to them.

IN the *Maritime Medical News* Maclarin states that ten English-speaking people are recorded as having acquired leprosy by residence in the leprous district of Nova Scotia.

THE regular meeting of the Order of Military Surgeons, of New Jersey, was held at the Medical Department, Headquarters Second Brigade, N. G. N. J., Sea Girt, on Thursday.

THOS. W. R. BISHOP, of Atchison, Kas., died in that city on July 17th after twenty-four hours illness, of what "two prominent physicians" pronounce "undoubtedly Asiatic cholera."

A YOUNG woman walked into the office of the Philadelphia Hospital last Wednesday, and requested admission to the Maternity Hospital. She remarked that it would be necessary to act quickly in the matter; and thereupon proceeded to demonstrate the entire truth of her proposition by lying down and having her baby then and there.

He is not a dentist any longer; he is an Orist.

Dr. Kölliker reports unfavorably of the use of pyoctanin in surgical practice.

St. Louis utilizes her bridge over the Mississippi as a sanitarium in hot weather. The breeze from the river renders it a pleasant spot.

The Committee of Charities of the Massachusetts Assembly has framed a bill requiring iron fire escapes to be constructed on the outside of all asylums for the insane throughout the State.

Dr. von Nussbaum, of the University of Munich, has received the Order of Merit of St. Michael of the second class, in recognition of his services as a teacher and a man of science.

In the Madras famine of 1877-8, at the Famine Relief Camp, 86 per cent. of the men and 83 per cent. of the women had wasted till they were barely two-thirds of their normal weight.

Dr. J. A. Woodward, of 1118 Walnut street, Philadelphia, had his room entered by a thief while sojourning at the Porter Cottage, Atlantic City. The doctor lost some valuable property.

A Canton street family ate some ham they had begged, and followed it up with bananas, onions, bologna and beer; and two doctors are trying to find out what gave them cholera morbus.

St. Vincent's Hospital, New York, is to be enlarged, shortly. A wing is to be built along Twelfth street, from the wall of the present building on that street, to the corner of Seventh avenue.

Mr. John Girvin, son of Dr. Robert M. Girvin, one of West Philadelphia's most prominent physicians, is sojourning at Bar Harbor. The doctor expects, also, to leave shortly for his vacation.

"Dr." A. Wilford Hall, the man who cures all earthly ills and ensures the hereafter by pumping a gallon of hot water into the rectum, has got into trouble by practising without being registered.

Dr. H. W. Mitchell, of New York, was robbed of his gold watch and chain and diamond ring, while bathing at Asbury Park last week; he had left them in the bath-room, from where they were taken.

Colonialism is exemplified in India, where, with its full opportunities for studying leprosy, they wait to legislate until England's physicians, who never see the disease, decide whether it is contagious.

The "epidemic wave" theory of influenza has been pretty generally knocked about by the late epidemic. The disease is still heard of as attacking places remote from the lines of travel, like Iceland.

The estimation in which the surgeon is held on an English ocean steamer may be seen by the comparison of his pay with that of other employés: Captain, $250 per month; chief steward, $50; chief cook, $60; baker, $50; saloon stewards, $25; firemen, $22.50; surgeon, $20.

St. Louis is dissatisfied with her census return; Supervisor Weigel having made it only four hundred and forty-eight thousand. Had she one or two hundred thousand paupers, anarchists, etc., as some other cities, she would be better pleased. She, however, should take comfort in the fact that though she is short on vulgar numbers, she is long on her tax returns, clearing house reports, number of new buildings, increase of manufactures, and in fact everything that goes to indicate prosperity, culture, home comforts, and a life worth living.—*Med. Mirror.*

Medico-Chirurgical College of Philadelphia.—W. C. Hollopeter, M.D., has been elected Lecturer on Diseases of Children; and Ernest B. Sangree, M.D., Director of the Histological Laboratory.

The W. C. T. U. has secured laws in all but eleven States requiring that scientific teaching relative to the effects of stimulants and narcotics upon the human body shall be given in all grades of the public schools.

A not wholly reputable party of three men and three women took a trip on the Delaware in a yacht belonging to a Dr. McGlaughlin, on South Fifth street, and while bathing, one of the women was drowned.

Dr. James Strawbridge, of Danville, died of apoplexy, July 19. He was a brigade surgeon in the late war; spent three months in Libby prison, and represented the Thirteenth district in the Forty-third Congress.

It has been authoritatively ascertained that nearly one hundred persons—mostly women—lost their lives in the dreadful holocaust at the Tongue Pointe Asylum. A large number have since died in consequence of the exposure.

Florence, Italy, is especially generous in medical charities. The Misericordia provides gratuitous nursing, food and care of children, and La Guardia gives medical attendance at all hours of the day or night, to all who are unable to pay.

The natives of New Holland perform oöphorectomy upon girls, to provide a class of prostitutes who will not unnecessarily increase the population; and in case of any natural defect, such as mutism, which they do not desire to transmit to posterity.

The *Medical Mirror* gives an excellent account of the Pittsburgh meeting of the State Society, but in one point we fear brother Love's gallantry failed him. He states that Dr. Bennet is in the neighborhood of thirty-five. We beg to state our belief that she is just twenty-nine.

Dr. M. H. Prowell, a druggist of Steelton, and a graduate of Jefferson Medical College, was convicted for carrying on the business of an apothecary without having obtained a certificate of competency and qualification to do so from the State Pharmaceutical Examining Board.

There is nothing slow about European medical journals when it comes to giving their readers the latest and most valuable news. In the *Dublin Journal of Medical Science*, for July, we find the mortuary records of British cities up to May 17, and the Dublin meteorology for May.

Contributions to the Sanitarian Association, a most worthy work, may be sent to Daniel Baugh, President, 20 South Delaware avenue; George D. McCreary, Market Street National Bank; John T. Bailey, 1136 Market street, or Dr. Eugene Wiley, 330 Reed street, Philadelphia.

Dr. R. C. Word, a prominent physician of Decatur, Georgia, died last Sunday. He occupied the positions of Professor of Physiology in both the Medical and Dental Departments of the Southern Medical College in Atlanta, and was for many years associate editor of the *Southern Medical Record.*

Drs. J. C. McKee, U. S. A., A. C. Bournonville, J. C. Hall., R. C. Agnew, O. H. Sternin, J. A. Fowler, of the *Scientific American*, W. W. L. Rickard,

W. L. Gillam, J. B. Maloney, J. M. Frese, M. W. Gilmer, T. D. Fairheller, H. M. Stokes, D. L. Adams, C. P. Turner, R. M. Keely, Jr., E. G. Shortlidge, of Wilmington, J. C. Morgan, Wiehle, and W. W. McClure registered last week at Atlantic City.

DURING the week ending July 19 there were 152 new applications for treatment at the Howard Hospital, Broad and Catharine streets. The number of visits to patients was 927, of which 126 were made by the Resident Physician to the patients' homes. The prescriptions given numbered 1,118, and the accident cases treated were 26.

THERE is said to be an opening for American dentists in India. In Madras there is no dentist for three hundred thousand people; and one has to travel one thousand miles to Bombay, where the only dentist uses no gold, and charges $7.50 a tooth.

We regret the opening is not for doctors, as nearly all our neighbors could be spared.

Merck's Bulletin for June exploits pyoctanin, the long-sought ideal antiseptic, which does all those things which it ought to do, and leaves undone those things which it ought not to do. Stilling has used it with marked success, especially in suppurative diseases of the eye. It is presented in the form of powders, ointment 2 per cent., pencils, etc.

THERE have been four hundred and forty-five cases of cholera infantum during the last two months; of these two hundred and fifty-one have been fatal. Last week the Board of Health declared the drainage of Wissahickon Inn and a private residence a nuisance, by reason of their discharge of sewerage into a tributary of the Wissahickon, which contributes to the city water supply.

CHILD-LIFE INSURANCE.—The Rev. Benjamin Waugh, whose name has become a household word in connection with child-life insurance, contributes an able and convincing paper on the question to the *Contemporary Review* of this month. He recommends as a remedy for this cruel kind of murder "that the handling of money benefit by a child's death be totally abolished, rendered impossible. Parliament must be called upon to make the system of child-life insurance as illegal as it is baneful. Let provision for funerals take its place, and, as in sick clubs, when a child is ill payment must not go to the parents, but to the doctor; so in burial clubs, when the child dies payment must go not to the parents, but to the undertaker. And let any tampering with the law be treated as what it now actually is, conspiracy to murder. Whether it be by societies, their agents, the undertakers, or the parents, it must be treated as a serious crime against both the bodies of children and the welfare of the State." We most heartily commend Mr. Waugh's humanitarian sentiments to the consideration of the Legislature.—*Med. Press and Circ.*

Is it an advantage or otherwise, that among the mountains there is no single resort that attracts the crowd, the lovers of excitement and bustle, as Atlantic City does? Rest, peace and quiet, social pleasure and restoration of health are the objects sought and found in the hills.

Delaware Water Gap is lovelier than ever before; and all the hotels are full of pleasant people.

Lake George is lined with Philadelphians. Dr. McCandless is at the Sagamore, Dr. J. N. Henry, of N. Y., at the Lake House, and Dr. J. D. Gorman, also of N. Y., at the Sheldon House.

Highland Lake, in its second year, has jumped at once into favor. Three large and good hotels, two thousand five hundred feet above sea-level, with beautiful scenery, within easy reach of the great cities, offer special attractions. Good fishing is to be found. Drs. Du Ford, Campbell and Koser, of Williamsport, Prof. Wormley, of the University, and Prof. A. C. Thomas, and their families, are among the guests.

Eagle's Mere is one of the places which, when one visits it one season, he comes back the next year and brings his friends. Cool nights, pure water, and fine bathing are among its attractions.

TO CONTRIBUTORS AND CORRESPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

RECENT ADVANCE IN THE RADICAL TREATMENT OF HERNIA[1].

BY NATHAN JACOBSON, M.D.,
Professor of Clinical Surgery, College of Medicine, Syracuse University; Surgeon to St. Joseph's Hospital, Syracuse, N. Y.

THE complete revolution in surgical procedures, occasioned by the appreciation of antiseptic and aseptic principles, has nowhere been more thoroughly evident than in the radical treatment of hernia.

In the American edition of "Holmes' System of Surgery," published as late as 1881, the word "radical" is, apparently with some justice, surrounded by quotation-marks. For there we find a quotation from Otto Weber, at one time the clinical assistant of Wutzer, the author of a very popular operation for the radical cure of hernia—which in substance is that he had never seen any of the so-called cured cases radically cured; and another, from Mr. Lawrence, to the effect that the radical operations for hernia afforded no prospect of recovery, though undertaken at the hazard of life, and that the patient after their performance, as before, was ever obliged to wear a truss.

Elsewhere I find the statement that Rothmund, in 1852, reported that of one hundred and eighty-one cases, treated by invagination, three had been permanently cured. The various operative measures, which had then been performed, and which formed the basis for these conclusions, were: invagination of the hernial sac by various methods; cauterization of the orifice and the neck of the sac; ligature applied around the neck of the sac; incision of the sac and subsequent healing of the wound by granulation; detaching the sac from its connections, and returning it into the abdomen; excision, suture and scarification of the sac; immediate and forcible compression of the sac by bandage and truss, and the use of stimulating injections, especially tincture of iodine.

Mr. Burkett, no doubt, expressed the best surgical thought of his day when he wrote the article referred to and spoke so disparagingly of the measure then in use for the radical cure of hernia.

Since 1880, however, there has been an universal effort on the part of surgeons in various countries, to devise an operation which should be alike free from danger to life and successful in being, in the fullest sense, a radical cure for hernia.

I assume that to be radically cured means that the patient should not only be relieved of the hernial protrusion, but that the parts should be so fully restored to their integrity that the further use of a truss is unnecessary.

While at times during the period mentioned, descriptions of various lines of operative procedure have found their way into medical journals, it has been only since the beginning of last year that various operators have published the results of their experience.

In passing upon the merits of surgical work that looks to the permanent relief of an affection like hernia, the true criterion must necessarily be the test of time.

How great a period must elapse before we can feel certain that the danger of recurrence of hernia has passed, is a matter under dispute.

Anderegg found that seventy-five per cent. of the recurrences occurred during the first year. Banks believes that at the end of one year one can speak definitely of the result. This period may not seem sufficiently long to many, yet I believe these state-

[1] Read at the meeting of the Third District Branch of the New York State Medical Association, at Syracuse, N. Y. June 19, 1890.

ments agree with the findings of those who have had opportunity for large observation. But whatever may be the views of individual physicians, as to the results to be obtained by the various methods of operation, it must be conceded by all that almost wonderful advance has been made under the modern methods of operation.

Foremost of all is the fact, which stands out in bold relief in the statistics of all countries, that the operations for the radical cure of hernia are no longer to be regarded as dangerous to life. In Schede's list[1] of fifty operations in free herniæ, one death is reported; and, as this patient died twenty-three days after operation, and five days after complete cicatrization of the wound, and as the post-mortem examination showed the death to have been caused by fatty degeneration of the heart, I believe it only just to say that there was not a single death attributable to the operation.

Svensson and Erdmann, of Stockholm, published in 1887 a list of one hundred and sixteen cases, without a single death; while Marcy, in his little work on "The Radical Cure of Hernia," published last year, writes that he will "warrant, in competent hands, a mortality not to exceed one per cent.," and, in a paper read by him last year, at Newport, quotes seven hundred and seventy-nine cases recently operated, with but five deaths, and these not referable to the operation.

This great step forward has made the next advance possible. The list of cases suitable for radical operations has been greatly extended.

At the meeting of the American Surgical Association, in May of last year, the almost unanimous expression of the surgeons present was that no operation for the relief of *strangulated* hernia was complete, except it ended with steps taken for its radical cure.

This is entirely in accord with the experience of foreign operators. Naturally, we look for a greater death-rate than when a radical operation is done for a free hernia. The condition of the patient, and particularly the condition of the intestine and the sac, seriously affect the prognosis.

And yet, even in this class of cases, the death-rate by no means approximates that which formerly attended herniotomy, when performed for the relief of a similar condition. For example, Bryant, in his "Practice of Surgery," states, where the sac was opened, at Guy's Hospital, the death rate was fifty per cent. in femoral, and sixty per cent. in inguinal hernia.

In one hundred and fifteen cases of strangulated hernia, operated upon by Schede for radical cure, eleven, or nine and one half per cent., died. Of these eleven, in only six was death at all directly connected with the operation. Of two, operated upon for inguinal hernia, death occurred, in the one case ten days, in the other eight weeks after complete cicatrization, both patients being old, the one sixty-one, the other eighty years of age. Of the three, dying after the radical operation following strangulated femoral hernia, one, sixty eight years old, died of exhaustion; one, sixty-nine years, of pneumonia; and the last of gastric hemorrhage from a cancerous stomach, two weeks after recovery from the hernial operation. The actual death rate, therefore, is but little more than five per cent.

This, surely, is a remarkable record. But, right here, the lesson which all this teaches cannot be too strongly emphasized.

[1] Zur Radikaloperation der Unterleibsbrüche. Von Friedrich Wolter. Leipzig, 1890.

It must be apparent that herniotomy for the relief of strangulated hernia, whether done alone or in conjunction with a radical measure, performed with the precautions that should surround all operations today, is, in itself, an innocent procedure. What renders its termination unfortunate is much more sure to be the mortifying or mortified condition of the sac contents, than any danger which attaches to the operation.

Taxis, long-continued or violent; unnecessary delay, either due to the timidity of the medical attendant, or occasioned by the use of measures which utterly fail of their purpose, are greater sources of danger to the patient, than can any operative measure possibly be, in the hands of the intelligent surgeon.

The selection of cases of *reducible* herniæ, suitable for operation, is one of some difficulty. The condition of the patient is to be considered. If the person be cachectic, be afflicted with phthisis or other serious disease, if he be advanced in years, it certainly would not be wise to operate. I had occasion, recently, to refuse an operation to a man who, because of long-continued suppuration, was suffering from amyloid disease of the kidneys and other organs.

If the hernia be thoroughly held in place by a truss, a radical operation is not indicated: although many operators prefer to except from this rule young children. Rothmund believes that if the wearing of a truss has not effected a cure in a child when it has reached its seventh year, it will not later. Tiffany, of Baltimore, is of the opinion that congenital herniæ should be operated if it is probable that the child will later in life be obliged to do manual labor. And this seems to be the view of many surgeons, abroad as well as in our own country.

But where the truss fails to retain the hernia and the individual is incapacitated for work, the radical operation is demanded.

Permit me now, as briefly as possible, to refer to the methods of operation to-day regarded with most favor.

With the advent of a clearer conception of what could be accomplished with the advanced methods, there came new principles of operative procedure.

Instead of the cautery and caustics, the complicated instruments and invagination, there came the knife; instead of subcutaneous operation, there was free exposure of the canal and the rings; instead of the effort to excite an intense inflammation at the hernial orifice to favor the development of a cicatricial plug, came to the minds of some the desire to secure union by first intention.

And yet, as to the latter proposition, the profession is still divided. There is the one class of operators which seeks the restoration of the parts to their normal condition by primary union, and the other which still believes that there is greater strength in the cicatrix, and who, therefore, after disposing of the hernial tumor, seek to delay repair, that union may occur by granulation. This latter is called the open wound method.

It will be impossible at this time to refer to every method of procedure that has been suggested for the disposition of the hernial tumor and the management of the canal and rings.

The details can best be summarized under several heads:

1. The disposition of the sac.
2. The treatment of its neck.
3. Splitting of the inguinal canal.
4. The suturing of the ring.
5. The closure of the wound.

(1) *The Disposition of the Sac.*—McBurney, in his paper before the New York Academy of Medicine, February 21, 1889, asserts that all concede that removal of the hernial sac is indispensable in securing the cure of a hernia.

While there is no doubt that most operators endorse this statement, this broad assertion is unwarranted. Macewen, the author of a very extensively-used operation, passes a suture longitudinally through the sac and out of the wound an inch above the internal ring, thus folding the sac up and drawing it into the abdominal cavity. By this means he believes he creates a bulwark at the abdominal surface of the internal ring, against which, to use his poetic thought, the intestinal waves may dash but be beaten back.

Schede does not believe in the universal application of this rule, not regarding it of prime importance in securing a radical cure. Umbilical hernia, he says, is best suited for sac extirpation, next femoral, and least of all inguinal. He further states that where the sac is very adherent, and especially when it is but little changed in character, union by first intention is not interfered with by allowing it to remain.

In operating upon congenital herniæ some American surgeons do not open the sac, but, placing two ligatures about it—one high up—exsect the intervening portion.

There is no doubt, however, that the extirpation of the sac greatly simplifies repair, lessens the period of recovery, and favors union without wound complications.

(2) *The Treatment of Its Neck.*—Czerny, in 1877, was the first to recommend ligation of the neck of the sac. This step is to precede the sac extirpation. For the purpose of its ligation the sac is to be opened, the finger of the operator carried well down to the internal ring, while tension is being made at the fundus. This, of course, can only be done if the sac be empty. Should there be intestine present, it is to be returned into the abdomen. If there be omentum, it is to be removed, after a ligature or suture has been applied at a suitable point, and the stump carried into the abdominal cavity. The sac now being empty, traction made at the fundus, a ligature is thrown about its neck, as high up as possible, while the operator's index finger, in the sac cavity, prevents the extrusion of the abdominal contents.

Nussbaum in Germany, and Marcy in this country, prefer stitching the neck to its ligation. The latter uses a curved needle, fixed in a handle, with an eye at its extremity, with which he makes the shoemaker's stitch, not only in closing the neck, but also in the subsequent steps of the operation.

But, whether closed by ligature or suture, the result is that a smooth peritoneal surface now marks the inner aspect of the internal ring. The particular point gained by this is that no dimpling into the internal ring exists into which intestine may be projected and favor the recurrence of hernia. Other methods of dealing with the neck of the sac are in use, especially that of Ball, who twists the sac upon itself at its neck several times, securing its quite firm occlusion, and then fastens it to the internal ring with sutures.

This plan, however, is considered too blind to be entirely free from danger.

(3) *Splitting of the Inguinal Canal.*—Some operators have contented themselves with ligaturing the sac at the external ring, drawing it down as well as possible. This procedure overlooks a very important anatomical consideration, namely, that it leaves patent the internal ring and inguinal canal, allowing the gut to pass into, if not through, the latter; and then we have a bubonocele.

Risel was the first to suggest splitting the inguinal canal, exposing the internal ring, and removing the sac at the point of its projection from the peritoneum.

This plan McBurney and Marcy have both adopted. Schede objects to it, saying that it is almost exceptionally bad and increases the danger of peritonitis. But the operators mentioned have found no reason for this fear.

It certainly gives greater exposure of the internal ring, better oportunity for freeing adhesions and separating the neck, and, as I believe, after operating in this manner, is of tremendous advantage to the operator.

(4) *The Suturing of the Ring.*—Concerning this step there has been no end of dispute. It has its advocates and opponents. McBurney argues that the ring is a permanently dilated opening in an inelastic fascia, and, therefore, the walls are very unyielding and nothing can be gained by this procedure. Anderegg and Lucas-Championiere take a similar view.

But whatever may be the opinion, based upon theory alone, of any operator, the fact is that all observers, who have followed their cases, have found that there is a very decided narrowing of the ring after its suturing. Its complete closure is assuredly not desired, for that would mean compression of the cord or round ligament. But the necessary reduction in size is obtained.

A variety of plans are followed. Macewen, with the needle that bears his name, carries a loop through one pillar, and fastens the threads together in the opposite one, carrying them through the corresponding points. Czerny prefers the purse string suture, with which he draws the walls of the rings together. Marcy, as has been said, uses the shoemaker's stitch. Others use an interrupted suture; especially is this the case when silver is employed.

Our own Gross was the first to attempt this step. This was thirty years ago. He used silver wire, and had a good result in two cases.

Much discussion has also occurred as to the material best suited for suturing. In 1874, Steele employed catgut. Czerny found this to be inefficient and substituted carbolized silk.

Perhaps the first to use the buried animal suture, in the radical cure of hernia, was Marcy, of Boston. In his hands its use began in 1870, and he has seen, as he personally informs me, no reason as yet to abandon it. His preference is for the tendon taken from the tail of the kangaroo.

In 1884, Banks asserted that his choice was for silver wire, and, since 1887, Schede has used only silver in all the radical operations he has performed at Hamburg, for closing the ring. This he buries, and finds that it remains permanently in place and undergoes no change.

Lastly, the Closure of the Wound.—Here we are confronted by the claims of those who insist that cicatricial tissue gives firmer support than can possibly be obtained by primary union.

McBurney, after he has laid open the inguinal canal, removed the sac and returned the stump into the abdomen, adapts provisional sutures to each side of the wound, carried through the walls and takes particular pains to roll the skin inward, that primary union shall not be possible. However, even he does not consider it wise to have too much cicatricial tissue, but applies tension sutures to so approximate the walls of the wound that the space between them shall be reduced to from one-fifth to one-quarter of

an inch. This done, iodoform is thoroughly dusted into and the wound packed with iodoform gauze most carefully; to protect the wound from the entrance of urine or feces, especially in children, rubber tissue is used as a protective dressing, or even a plaster of Paris bandage, while the catheter is employed for several days. But here also, prohibitory measures do not always prohibit.

The dressings are changed every five or six days, and as many weeks are required for the closure of the wound by granulation.

This plan of treatment, judging from the discussion that followed the reading of his paper at the Academy of Medicine, and that which took place at the meeting of the American Surgical Association last year, seems to be the one most generally pursued by American surgeons.

The open wound method is quite favorably regarded abroad also, especially in England.

As strong supporters of the plan which aims at primary union, we have Marcy, in this country, and many German surgeons. The former uses the kangaroo tendon also for the closure of the wound, accomplishing it with successive rows of continuous suturing, closing every recess with the shoemaker's stitch, until he reaches the surface. Then he employs a blind stitch, which is a continuous suture, including all but the superficial layer of the skin. When his operation is completed, no suture therefore is in sight, and the line of incision appears to be but little else than a scratch; of course, no drainage is required. The only wound dressing that follows is a coating of iodoform collodion.

Küster, too, recommends the continuous suture for closing; but Schede prefers an interrupted suture of No. 1 catgut. His objection, and my experience has taught me its validity, is that the tension of a continuous suture is apt to endanger the circulation and thus interfere with primary union.

As to the comparative value of these two methods, perhaps time enough has not elapsed to decide.

Yet it is most remarkable how wonderfully well Schede and Marcy agree in the statement of the results of their methods. For while the latter says in his paper before the American Medical Association last year that "of those whose histories I have a knowledge, fully ninety per cent. are permanently cured, and in no instance do I advise the subsequent wearing of a truss." Schede's statistics show that of the one hundred and sixty-five operated, recurrence occurred in but fifteen.

It certainly is the best possible endorsement of an operation to have two operators, as widely separated as these, differing in some details, but striving for the same end, working independently of each other, as I know to be the case here, reach conclusions so thoroughly alike.

Whether the open wound treatment will make as good a showing, time alone can tell. That it will do better we all may reasonably doubt.

There are many other points that might be presented. But as my purpose was simply to call the attention of the association to the great advance that has recently been made in treating an affliction so universal as hernia, the safety with which the operations can be performed, and the assurance of radical cure they offer, I shall not detain you longer.

THE Siberian cattle plague is ravaging the province of Riazan, in Russia; a number of peasants, also, have contracted the disease, but no fatal results, so far, have been reported.

MEDICINE: PAST AND PRESENT.[1]

By H. O. JEWETT, M.D.,
CORTLAND, NEW YORK.

THE fundamental principles of a positive science are unchangeable—as truth is the same yesterday, to-day, and forever.

Medicine is not a positive science; and it would be gratifying to believe that the changes observed in the theory and practice of our art were only the changes incident to progress and improvement. But, when we contrast the heroic antiphlogistic treatment of disease which was in vogue three-quarters of a century ago with the tonic, stimulating, sedative, anodyne, and, I may say, semi-expectant practice of to day, it naturally suggests one of the following conclusions:

1. That those earlier practitioners, whom we are proud to recognize as the great lights in medicine, and than whom no more devoted and discriminating minds ever delved in any field of science, were wholly at fault in their methods of investigating morbid phenomena, their interpretation of symptoms, their theories of the *modus operandi* of remedial agents, and their estimation of the tolerance of the vital powers; as well as in their observation and record of the results of their practice.

Or, 2. That our race has, during the last hundred years, greatly deteriorated in constitutional vigor and power of endurance; thus diminishing its tolerance of depressing influences, either in the form of disease or of active remedial measures.

Or, 3d. That nearly or quite all of the diseases of our country, especially our acute inflammatory and febrile affections, while exhibiting the same general aspect, the same semeiological phenomena, have, nevertheless, passed from a sthenic to an asthenic type, with an increased tendency to early prostration and collapse.

Now, are these, or is either one of these, inferences actually tenable?

Without going back to remote antiquity and referring to the great—who were great only by comparison with the uneducated masses—shall we repudiate or ignore the experience, the observation, and the doctrines of such men as Abernethy, John Hunter, Sir Astley Cooper, the Bells, Rush and Physick, names which have come down to us, and will go down the ages surrounded with a halo of glory for their grand achievements in medicine and surgery?

> "Shall we call our fathers fools, so wise we grow?
> No doubt our wiser sons will call us so."

It should not be forgotten that while these men were without the wonderful facilities which we enjoy, they were devoted students and critical observers of nature. They resorted not to text-books or medical literature, but to the fountains of nature for their facts. Their conclusions were drawn from that most infallible source of all positive knowledg: personal experience.

They had not utilized the microscope or the clinical thermometer, and though they had some crude ideas of the septic origin of disease, they had never hunted the bacteria and the various tribes of microorganisms which have revealed themselves to modern pathologists. Hence they had no occasion to discuss antiseptics, germicides and parasiticides.

It is doubtful if they had ever pronounced many of the classical and technical terms of our modern vocabulary, designating the results of recent investigations in histology, etiology, and pathology. But,

---

[1] Read before the New York State Medical Association (Third Branch), at Syracuse, June 19, 1890.

if they were deficient in the finer accomplishments of a scientific practitioner of to-day, their native tact and large experience rendered them expert in the main essentials of successful practice. They were at least familiar with the signs of life and health, and could readily detect the signals of disease and impending dissolution.

They could determine with a great degree of certainty whether their patients were destined to live or die, to recover completely or remain confirmed invalids.

Their materia medica was limited but efficient, their therapeutics comparatively circumscribed. Sir Astley Cooper once said, "Give me the lancet, antimony, calomel, opium, and bark, and I will make them adequate to all the ends of practice." These were their sheet-anchors, and they knew well when and how to cast them.

In these they had a direct antiphlogistic, a narcotic, a nervine, a diaphoretic, an emetic, a cathartic, an alterative, and a tonic.

Opium would allay pain, bringing comfort and solace, and sleep to the sufferer.

Antimony would excite the functions of the skin, equalize the circulation of the blood, relieve internal congestion, thereby banishing the dyspnœa of croup and the oppression of pneumonia.

Calomel would flush the sewers of the alimentary system, and "shake the gall-bladder with a vengeance."

Timely, bold, efficient venesection would dispel the pangs of pleurisy, the contortions of eclampsia, the maniacal raving of phrenitis, and the stertor of apoplexy.

Whatever may be said of the crudities of "ye olden time practice," our fathers bearded the lion in his den, grappled disease by the forelock and throttled it. Their motto was "*pugnatum est arte medendi*," illustrated by a figure of the goddess of medicine armed with a baton, belaboring the head of the serpent.

If they were at times somewhat hyperheroic in the use of depletives, it is a question whether they could not honestly report as large a percentage of cures as we can of recoveries under our more temporizing treatment.

Doubtless there were charlatans then as now, who pursued a routine course with active remedies, doing much more mischief than they could have done with our modern placebos in the form of sugar pellets and infinitesimal dilutions. They were the blind man armed with a club. If he hit disease, it received a terrible set back, and possibly passed for a marvelous cure; but if he hit the patient, it was a visitation of God.

But such have no place in history save as miserable excrescences upon the "*corpus medicale*," just such as we see at the present time.

In reference to the second inference, recorded facts do not by any means justify the conclusion, that, under our advanced civilization, the human race has in any measure deteriorated in vital force and power of endurance during the last hundred years.

On the other hand it is shown by well authenticated statistics, that throughout nearly all of the civilized and enlightened portions of the globe, the longevity of man has progressively increased.

A better general understanding of the laws of life and health; better sanitary regulation; better ventilation of dwellings; better food; better clothing; the lessening of arduous hand labor by the application of machinery to the purposes of agriculture and mechanics; a greater number of hours devoted to rest and recreation, thus abating the severity of toil, and relieving the monotony of existence among the laboring classes.

All these things have tended to prolong the activity of youth and the vigor of manhood, so that, despite all the evils of luxury, and the multiplied casualties from the use of steam in manufactories and upon railroads, and the application of subtle chemicals to the arts, the average duration of human life now exceeds that of preceding generations.

It may also be observed that, making all due allowance for the benign influence of anæsthetics and antiseptics in avoiding the shocks of pain and averting untoward sequelæ, men, women, and children sustain severe injuries and dangerous mutilations, by accidents and by surgical operations, recovering therefrom with greater certainty and celerity than at any former age of the world.

I believe that the sound, healthy man of the present generation will endure more, and accomplish more in a life-time than could his progenitors of one or two hundred years ago.

As to the third inference alluded to in the beginning of my paper.

There is some evidence that our local inflammatory and febrile affections have, within the last century, assumed more of a typhoid and asthenic type, with a corresponding intolerance of active antiphlogistic treatment; a change due possibly to our artificial habits of life, to climatic changes incident to the transformation of a vast wilderness into cultivated fields, or more probably to some combination of causes not well understood.

But it must not be forgotten that Asiatic cholera, yellow fever, typhus and typhoid fever, *morbus-strangularius* and cerebro-spinal meningitis, or "spotted fever," displaying all their wonted tendency to early prostration and collapse, prevailed in many parts of the world, long before the days of Rush and his distinguished contemporaries.

Even these diseases were treated with reputed success by sanguineous depletion.

It is recorded of the celebrated Dr. Dover, physician and buccaneer, that, just before taking by storm the two cities of Guayaquil, the plague broke out among his forces, and in less than forty-eight hours he had in his several ships one hundred and eighty men down with the disease. He ordered his surgeon to go round with the whole number, opening the veins in both arms, with the command to leave them bleeding till all were blooded, and then go round in the same order and tie them up. Thus they lay bleeding and fainting so long that he says, "I could not conceive that they lost less than one hundred ounces each man." Notwithstanding he had one hundred and eighty odd men down with that most fatal malady, and though some of the poor fellows bled nearly, or quite to death, he lost only seven or eight in all, and he "made no question that, with ordinary medical treatment, considering the heat of the climate, and the exposure to which they were subjected, he would have lost nearly every man."

Such was the testimony of one of the shrewdest practitioners of his time.

Dr. Dover was a bold man, but it might require a bolder than he to enforce that sort of treatment now in this latter part of the nineteenth century.

Nevertheless, if such practice were sound and successful one hundred years ago, it should be equally successful under similar circumstances at the present day. And I believe that a large percentage of our acute inflammatory affections will not only bear, but be benefited by, a liberal use of the lancet.

Prejudices in religion and medicine are always potent and far reaching; and fashion rules about as arbitrarily in medicine as in millinery.

The members of our profession throughout the country, in yielding to the prejudice of society, and to the beck of fashion, often against their own convictions, have nearly abandoned and consigned to the tomb of the lost arts, one of the most invaluable and efficient life-saving agents we have at command. In acute pleurisy, in the early stages of pneumonia, in puerperal eclampsia, and in many cases of cerebral congestion, no other remedy will begin to compare with prompt, well-timed venesection. In fact, I have never seen such cases recover as happily and as completely under any other plan of treatment.

Do we fear dangerous prostration from the loss of a few ounces of blood, in the face of a disease which we know, if unchecked by some vigorous measures, will certainly overwhelm the powers of life?

In our obstetrical practice we have witnessed pretty copious *post-partum* hemorrhage without much alarm.

We have seen a half-vesselful of the vital fluid from the parturient woman without a sign of syncopea, and this, too, after the prostrating effects of a protracted labor. And, moreover, we have seen that patient recover better and more rapidly than many others who have flowed less.

It is a besetting sin of physicians that they mingle and confound speculation with facts, making facts subordinate to speculation.

A rigid adherence to facts will convince us that the apprehensions of dangerous prostration from judicious venesection were never born of experience and observation.

Dr. Rush used to assert that an "apparent prostration, like that observed in syncope, was often mistaken for extreme debility; and that the cure of a malignant fever was always most complete, and the convalescence most rapid after blood had been drawn till the face became, and remained, very pale."

Those of us who have practiced as we were taught many years ago, and who have witnessed the marvelous effects of a single bleeding, as an abortive measure in acute inflammation, and have observed the rapid convalescence which followed, without even the aid of adjuvants, may be pardoned for the faith that is in us.

I can remember when we did not expect to lose a case of pneumonia after early and efficient bleeding, and it was almost an accepted axiom that a case of double pneumonia, which would not bear bleeding, would be fatal in any event.

In those days we bled in pleurisy, and our patients recovered perfectly in a few days. I venture to say that not one case of pleuritic abscess or effusion occurred where there are twenty now. The trocar was not called into requisition to help nature repair the mischief which the lancet could have averted.

But human judgment is fallible; statistics are not always reliable, and coincidence are sometimes mistaken for cause and effect. "*The post hoc for the propter hoc.*"

If the practice of medicine has at times been unnecessarily, even harmfully energetic, it is no reason why we should switch off upon the unballasted sidetrack of homœopathy or expectancy, resolving to do no harm by doing nothing at all.

It is no fault of an important principle that it has been misapplied, or of a useful remedy that it is potent for evil as well as for good.

If we were to discard every article which is capable of mischief in ignorant and unskillful hands, we should effectually emasculate the materia medica and cripple our therapeutics.

But I am somewhat of an optimist, believing that despite the conflicting theories which have always tended to handicap and retard the advance of science, the true eclecticism of our art will yet sift the wheat from the chaff, bringing truth and heresy, fact and fiction, which have appeared like the confused colors in a kaleidoscope, into order and arrangement, making them contribute to our stock of useful knowledge.

Contrary to the axiom of "nothing from nothing," and in accordance with the trite simile of the bee gathering sweets from unsavory and malodorous flowers, we have already learned something of value from the vagaries and absurdities of Perkinism and homœopathy. The latter a system which, by a rigid practical adherence to its fundamental dogmas, should have perished in a twelve month, and which now only subsists upon a name and what it has pilfered from the practice of rational medicine.

But homœopathy has at least demonstrated the marvelous power of the imagination over physical infirmities, and the spontaneous cure of disease. We have learned that a great number of maladies, not heretofore so regarded, are in fact self limited, and to a great extent self-curative—that perhaps three-fourths of those which we are called to treat, would, with careful nursing, proper hygienic regulations, and a removal of all offending causes, recover without the aid of the materia medica. How much valuable time may be saved, and how much danger and suffering averted, by timely and judicious medication, is another question. As students of nature, we may congratulate ourselves upon our good fortune in having been born when we were, though I would like to have made my advent a little later in the century.

We live in an age when all the systems of nature are disclosing their mysteries, and all the avenues of mind are open to receive them. When everything that contributes to the comfort and welfare of man—everything which makes modern civilization what it is—is rapidly advancing, and when medicine is, in the language of sportsmen, "neck and neck in the race" with the sister sciences.

In an age when we make the sunbeams paint our pictures, when we travel, dispatch, converse, illuminate our streets and dwellings, besides transmitting the souls of our culprits to "Kingdom Come," by lightning, surely the limits of the possible are undefined and undefinable.

As physicians, with a vast wealth of professional knowledge, born of the centuries, for our birthright and our starting point; with multiplied facilities for investigating the laws of life; with greatly improved methods of detecting the physical signs of disease; with all that the thermometer, the microscope, the laryngoscope, the ophthalmoscope, the test-glass, and a hundred other cunning contrivances have accomplished in the hands of enthusiastic laborers in the fields of histology and pathology; with all that chemistry and pharmacy have effected in supplying us with a vastly improved and amplified materia medica, we should, we ought to practice better and more successfully than did those who lived fifty or a hundred years ago; just as the steam engine and the telegraph are expected to outstrip the old-fashioned mail coach and common vehicle of our fathers.

But with all these superior advantages, whatever we may have achieved in the way of mitigating suffering and promoting euthanasia, have we made corresponding progress in the art of curing disease, which is the crowning glory of our noble calling?

We have certainly accumulated much valuable material to be utilized by those who shall come after us, just as the miner furnishes nuggets to be coined and fitted for circulation by the artisan of the mint.

It is, however, a pertinent question whether all our seeming advancement is in the direct line of improvement.

Is the plethora of our medical literature, an ambition on the part of correspondents to appear in print, prompting to the publication of reports booming fresh therapeutical means and measures; the promulgation of callow and unwinnowed theories, based upon a limited observation of supposed results? Is the multiplication of technical phrases and terms for the designation of newly-discovered substances and tissues, and the expression of varying phases and shades of vital and morbid processes, any aid to science? Or do they tend to confuse the mind of the student, and tax the memory of the practitioner, to the exclusion of important facts and principles, as it were, "tithing *mint* and *anise* and *cummin*, and all manner of herbs, and omitting the weightier matters of the law?"

Is the rapid expansion of our pharmacopœia an unmixed good? The multiplicity of advertising circulars, proclaiming the superior virtues of new preparations, which come to us unsolicited through the mails, to litter our tables and fill our waste baskets, are they any profit or convenience to the busy practitioner?

It is in accord with the progressive spirit of the times that many of the crude and bulky articles which once filled the shelves and freighted the saddle-bags of the doctor—the powders, boluses and decoctions, which were so repulsive to the senses of the valetudinarian, should give place to the more delicate and refined preparation of modern pharmacy.

But life is too short, and too precious, to experiment with all the multitude of extracts, elixirs, syrups and alkaloids, the protean forms of pharmaceutical compounds and formulas so pertinaciously forced upon our attention through the enterprise of manufacturing chemists.

And besides, do not these tend to foster a pernicious system of polypharmacy, muddling and embarrassing our appreciation of the specific effects of individual remedies? Do they not encourage a lazy habit of adopting the diagnoses and prescriptions so conveniently furnished us by the dealers in drugs? "The practice of medicine made easy," as it were, thus shirking the wholesome mental discipline and the noble responsibility of thinking for ourselves?

Modern researches in medicine have extended in so many different directions, embracing so wide a scope, that no ordinary mind can command a thorough knowledge of the science in its totality. Hence the necessity for a division of labor, in order that an individual may select a branch best adapted to his taste and ability, and by devoting to it his entire energies, attain a degree of perfection, which can never be reached by the general practitioner, who must earn his bread by a mixed practice in the country.

The operating surgeon, the oculist, and the gynecologist, if they have chosen well their parts, by constant practice therein should and do acquire a degree of skill and dexterity far surpassing that of the ordinary physician.

We owe much to the labors of the chemist, the microscopist and the pathologist in developing their respective branches.

The special study of mental diseases has been productive of incalculable good. A better acquaintance with the laws of mind and with the intricate causes which conspire to produce and perpetuate these fearful maladies, has excited interest and awakened sympathy in the hearts of the public, thereby banishing the iron bars, and bolts, and chains, and collars, and cribs, and other barbarous means of physical restraint, and introducing more rational and humane methods of managing the insane and the idiotic. Philanthropic societies have espoused the cause of these unfortunates, learned men have given their attention to the subject, and specialists in this department have become sufficiently expert to mystify courts and confound jurors—and if confusion of evidence is the criminal's hope, the assassin, who pleads insanity as a defence, is surely not without a well grounded hope.

When I speak of specialists as a necessity I refer to the educated class, who are good general practitioners, and who are sufficiently learned to comprehend the relations of morbid phenomena, the reflex action and remote sympathies which influence nearly all local affections; not including those who view the world through a pin hole, and can see nothing outside the narrow vista which centers upon their one idea.

If a specialist be a charlatan he is likely to be the veriest of very charlatans. The chiropodist who ascribes a cataract in the eye to an ingrowing toe-nail; the neurologist who can trace the cause of chorea, locomotor ataxy, epilepsy, and the whole class of neuroses to a trifling ocular deviation—and worst of all, that professional and social pest who advertises for the treatment of female complaints, exploring the vaginas of all his patients, from the age of eight to eighty, in search of displaced uteri and ulceration of the cervix, which, by the way, he always finds; these moral (or immoral) plagues have become too common and well known to require extended comment.

Advancement in surgery has been more marked and positive.

More than seventy years ago Sir Astley Cooper performed the boldest operations that had ever been attempted, and was afterwards knighted for removing a harmless wen from the scalp of George the Fourth. It was the magnitude of the personage, not the operation, which secured him the distinction. John Bell has been styled the great fountain of surgical knowledge, and it is asserted that time has added little of importance to what he taught. He instituted what may be called modern treatment of wounds and traumatic aneurisms, suggesting the use of antiseptics to avoid pyemia, using the word antiseptic as it is used at the present time.

Those men were far in advance of the age, but if they were now to rise from the dead they would be amazed at the progress of operative surgery since their demise.

More diversified experience, increased facilities, and improved methods and means, including anæsthesia and antisepsis, have so extended the possibilities of our art as to bring within the domains of legitimate, every day surgery, operations which, but a few years ago were performed, if performed at all, with doubtful propriety, and in the seclusion of a hospital.

We no longer hear about trespassing upon nature's forbidden grounds, since scarcely any part of the human body, subject to disease or traumatism, is now beyond the reach of surgical skill.

The trocar and the scalpel explore the great cavities of the body with frequency, and with a safety heretofore undreamed of. The vault of the cranium is lifted in search of the demon of epilepsy, while the laparotomist enters the abdomen with as much con-

fidence as the dentist extracts a molar, and deep-seated vital organs are explored with comparative impunity. Confidence, born of knowledge and skill, has rendered these operations safe and feasible. Of course many of them could not be accomplished without the aid of the letheon, which is not only the patient's but the surgeon's supreme benefactor.

We who have seen capital operations performed without anæsthesia, and have witnessed the shrieks and convulsions which blanched the faces of students and communicated a tremor to the hand of the coolest operator, can well appreciate the boon.

With all the extraordinary advantages which science has furnished us, certain intrinsic qualities, knowledge, sound judgment and native tact, must fit the surgeon for his duty.

Whoever undertakes a difficult and dangerous operation without an unclouded comprehension of the relative anatomy, the pathology, and the special indications of the case in hand, is guilty of a crime, however mere luck or chance may determine the result of a groping procedure.

In all important surgical, as well as medical practice, the one constant element of safety and success is an accurate diagnosis, diagnosis, and again DIAGNOSIS.

REPORT OF TWO CASES OF SEVERE VOMITING OF PREGNANCY.

By E. W. MITCHELL, M.D.,
AVONDALE, CINCINNATI, OHIO.

IT is the purpose of this paper to present merely a clinical study of two cases without entering upon the voluminous and oft-rewritten literature of the subject.

CASE I.—Mrs. P. S.; of nervous temperament; delicate from childhood, but subject to no special organic disease; married at the age of twenty-six, and became pregnant within a few months. Nausea and obstinate vomiting developed early. Apparently, nearly all nourishment taken was rejected. She soon became so much prostrated as to be confined to her bed. Her weight, in a few weeks, fell from one hundred and two to seventy pounds. Local examination revealed the signs of an early pregnancy; a conical and very long cervix; no displacement or peri-uterine tenderness. Under treatment by rest in bed, careful regulation of diet (most of the time an exclusive milk diet), bromide of potash, and oxalate of cerium, the vomiting was somewhat mitigated and nutrition maintained.

At three and a half months the vomiting ceased; she regained most of her weight, and was in fairly good health during the remainder of her pregnancy.

Following a natural but tedious labor she had postpartum hemorhage, and on the third day the development of puerperal septicæmia. For many weeks she hovered between life and death, with a very high temperature and extremely rapid pulse. Recovery was tedious and imperfect, the patient being left with a weak and irritable heart and a shattered nervous system.

Six years later (in 1888) having but partially regained her health, she became again pregnant, and, as before, soon began vomiting and to lose strength rapidly. More distressing even than the vomiting were constant nausea and gastralgia.

There was no uterine displacement, no peri-uterine tenderness; there was about the same as the usual softening, except at the point of a laceration sustained in the first labor, which was hard. The urine contained no albumen, casts, or sugar.

After three weeks' treatment upon the same plan as before, during which there were variations for better and for worse, but a gradual loss of strength upon the whole, it was decided, in consultation with Dr. T. A. Reamy, to induce abortion.

This decision was made not only upon the threatening character of the vomiting present, but upon the previous history of ill health and the rapid loss of strength. Since the nausea and vomiting were no worse than in the first pregnancy she might have survived, and, as before, ceased vomiting at the end of three or four months. The chances, however, in her already enfeebled condition, of living through another pregnancy and parturition were too small to justify the risk. The pregnancy was now so far advanced that it could—in this case—be positively diagnosed; to wait longer was to incur great danger of the patient becoming too far reduced to rally after an abortion. As the patient's condition was such as to allow some delay, electricity was selected as the means, being considered the safest, although slower and less certain than some other methods.

A daily séance of fifteen or twenty minutes of the Faradic current, as strong as could be comfortably borne, was given, for six days. One pole was placed over the abdomen; the other, a uterine sound, introduced, with antiseptic precautions, into the cervix—not through it.

Soon after the sixth application uterine pains with slight hemorrhage came on, and the fœtus was expelled in about five hours. The placenta not following promptly two fingers were introduced, and the already loosened placenta easily removed. A few adherent fragments were removed by the curette, and the uterus irrigated with a $\frac{1}{3000}$ bichloride solution. The fœtus was apparently of about twelve weeks' gestation. After the third or fourth application of electricity there was an amelioration of the vomiting, complete relief after the abortion, and prompt recovery to as good a state of health as preceding the pregnancy.

Her general health has since very considerably improved.

CASE II.—Mrs. C., aged twenty-seven years, a slender brunette of nervous temperament; has never been very strong; prior to marriage had been treated for "falling of the womb" and "ulceration," and had had two attacks of "inflammation of the bowels"—probably pelvic peritonitis.

Came under my care—having recently removed from a distant city—June 10, 1889. Married two years; one child nine months old.

The first three and a half months of her first pregnancy had been marked by very severe vomiting, with emaciation and prostration sufficient to confine her to bed. It had ceased at the end of that time, and she had been well during remainder of pregnancy. Labor natural; convalescence prompt and good; general health better since than before.

Menstruation returned four months after delivery; was regular up to period due May 8, which did not appear. Two weeks later began to have vomiting, which grew gradually worse. At the time of my first visit she was vomiting after each attempt to take food or drink, with occasional retching when nothing was taken.

Stated that she had been vomiting and retching almost incessantly for over two weeks. The countenance wore an anxious expression and was slightly jaundiced; tongue coated, with red margins; breath offensive; slight salivation; had lost much weight; complained of backache, severe pelvic pain, free leu-

corrhœa; bowels, constipated; vesical tenesmus; temperature, 99°; pulse, 90, fairly strong.

Vaginal examination: Uterus enlarged, corresponding to six or eight weeks' gestation, not displaced; cervix, lacerated on one side, with deposit of some cicatricial tissue in angle of rent; great tenderness to pressure about whole vaginal vault; no erosion of os.

Ordered: Nothing to be taken by mouth except carbonic acid water and oxalate of cerium, gr. 4 every three hours; *per rectum*, beef peptonoids with chloral hydrate and bromide of potash, each gr. xxx.

11 P. M.—Rectal injection not retained; vomiting and retching violent every few minutes; much exhausted; complains of "pain in the womb." Ordered: Nothing per os; an opium suppository, which gave relief in about half an hour, when an injection of 2 oz. of beef peptonoids was retained. Rested well until 4 A. M., when bowels moved and vomiting recommenced.

June 11.—Gave, in morning, vaginal douche of hot water, on account of peri-uterine tenderness; rectal injections not retained; vomiting and retching so incessant and suffering so great that gave morphine hypodermically, gr. $\frac{1}{3}$; and in the afternoon an opium suppository, followed in an hour by an injection of peptonized milk, which was retained. Vaginal douche repeated, followed by packing of wool saturated with boro-glycerine.

In four hours rectal injection of peptonized milk, with bromide and chloral, āā gr. xxx repeated. Temperature, 99°; pulse, 90. Injection not retained. During evening was not vomiting, and felt stronger. Slept from 11 to 1 o'clock.

June 12, 7 A. M.—Vomiting began again at 1 A. M. Temperature, 99°; pulse, 90. Still takes nothing by mouth; retching not quite so severe as yesterday; given morphine, hypod. gr. $\frac{1}{4}$, to be followed in one hour by wine-glassful of peptonized milk. 11 A. M. Has slept a little; milk was immediately vomited; retching occasionally. Morphine repeated: rectal injection. 2 oz. peptonized milk with bromide and chloral, āā gr. xxx; vaginal douche, followed by packing; ordered bromide of potash, gr 4, with half wine-glassful of iced champagne every two or three hours. Rectal injection retained. 5 P. M. She had rested fairly well up to 3 P. M. Now vomiting mucus streaked with blood; temperature, 99° (ax.); pulse, 90: the vomiting is not for some little time after taking the champagne and bromide. Ordered: Ice-bag kept on hypogastrium; champagne and bromide continued, also, the following suppository *per vaginam*: Ext. opii, gr. 1; ext. cannabis ind., ext. belladon. āā gr. $\frac{1}{3}$. For two hours after applying the ice-bag had no vomiting. 11 P. M. Again retching violently, and vomiting up mucus streaked with blood; hypodertic injection of morphine, gr. $\frac{1}{4}$, given. In few minutes relieved and a little hot water was retained. Rectal injection of peptonized milk at 6 P. M. was retained; now repeated, but not retained.

June 13.—Has kept on ice-bag and taken champagne and bromide; at 4 A. M., rectal injection (not retained), peptonized milk and a suppository per vaginum; at 7 A. M., vaginal douche of hot water and one of above suppositories per rectum. 12 M. Has retched and vomited a little; champagne and bromide retained and enjoyed by patient; nothing else given by mouth; is brighter and a little stronger; temperature, 98° (axillary); pulse, 90. Urine—as throughout—contains neither albumen, casts, or sugar; somewhat diminished in quantity. Rectal injection peptonized milk with bromide and chloral, āā gr. xxx, not retained. 10 P. M. Again vomiting and retching violently; seems greatly prostrated; anxious expression; seen by Dr. Reamy in consultation, who introduced the index finger into cervix up to internal os. Champagne and bromide and the suppositories, *per rectum*, continued; ice-bag put on nape of neck.

June 14.—Slept fairly well; vomited twice only during night; had two suppositories during the night; feels better; temperature, 98°; pulse, 115. 12 M. Has twice retained 1 oz. of milk, with champagne and bromide; suppositories per vaginum every three hours. 7 A. M. A little retching occasionally; no suppositories during afternoon.

June 15.—Rested well; is brighter and stronger; vomited twice during night, but not violently; retained peptonized milk; ice-bag kept to nape of neck; bromide and champagne continued; suppositories given twice during night and in early morning. 7 P. M. Retains milk given in small quantities; very little vomiting.

June 16.—One severe attack of vomiting; two suppositories during day; other treatment continued.

June 19.—Has continued to steadily improve; taking milk in small quantities; a suppository once or twice daily; no vomiting; occasional nausea; diet enlarged a little.

June 20.—Stopped bromide and suppositories; milk, ice-cream, and beef steak retained; has a slight uterine hemorrhage.

June 21, 5 A. M.—Free hemorrhage; uterine pains; fœtus already expelled and lost; placenta in cervix, removed by fingers, a few adherent fragments removed by curette and uterus washed out with carbolized solution. Placenta was apparently of about ten or twelve weeks. Convalescence was good. Some three or four weeks later she complained of pelvic pain and backache.

Examination revealed subinvolution of vagina and uterus, slight prolapsus, and a tender mass to the left of the uterus the size of a hen's egg. After several weeks of treatment by douches, tampons and galvanism, involution was complete; position of uterus about normal; the mass greatly reduced in size, not tender to touch; the patient free from subjective symptoms. She has since remained well.

When so many remedies are used, as in this case, it is difficult to decide as to the real effect of any one. Bromide of potash and chloral *per rectum*, so highly commended by Dr. Busey, (*American Journal Medical Science*, 1878, p. 140), and others, had little effect in this case.

Rectal feeding was in this case partially successful, but the nutrient injections were only retained when she was under the influence of opium.

One application to the os of nitrate of silver was made, but not repeated because no apparent benefit followed, and there was no inflammation or erosion. Ether spray to hypogastrium was also without benefit. The ice-bag gave so much relief that the patient clung to it almost constantly after its first application. It did not, however, stop the vomiting, except for a short time at first.

The iced champagne was very grateful to the patient and was retained when other things were rejected.

The only remedy which stopped the vomiting was opium, by suppository or by hypodermic injection of morphine. Vomiting would, however, return as soon as the effects wore off, and it was necessary to gradually increase the dose.

In some reported cases, it has failed to control the

vomiting, or finally loses its effect when it has been successful at first.

Except as stated in the report, remedies by the mouth were avoided. When the case has reached this stage to persist with internal remedies is not only useless but aggravates the trouble.

Since Copeman reported his success with the method, (*British Medical Journal*, 1875), dilatation of the cervix by finger or instruments has been often used with success. So often, indeed, that Dr. Gill Wylie claims that rigidity of the cervix is nearly always the cause of the vomiting, and that the cases of failure are due to the dilatation, not having been done thoroughly enough. When the first dilatation fails, he repeats it. (*Medical Record*, 1884; "Trans. Amer. Gyn. Soc.," Vol. 13, p. 259.)

In discussing an able paper upon the subject, by my friend, Dr. G. S. Mitchell, in the Cincinnati Obstetrical Society, Dr. Reamy reports that since 1872 he has so treated thirty cases, with success in two-thirds. He, at the same time, points out that the cases adapted to the treatment, and in which it is successful, are those in which there is rigidity of the os. (See *Cincinnati Obstetrical Gazette*, 1885, p. 118.)

Abortion not unfrequently follows, and hence the procedure should be reserved until other means have failed, but not delayed until the patient is too greatly exhausted.

As bearing upon etiology, we note in both these cases the absence of displacement. In each a lacerated cervix with some cicatrical deposits. The softening of the tissues about the os externum, was about as much as we are accustomed to find at the corresponding periods of pregnancy, except just at the point of laceration. Both had histories of preceding inflammatory attacks. Both were delicate women of nervous temperaments. In neither was there any evidence of "endometritis gravidarum," to which as a cause, in some cases, attention has been drawn by Veit, Ebell, Jaggard, and others, the placenta in both being quite healthy; and neither had any history of endometritis.

The tube-ovarian disease, discovered in Case 2, may have existed previous to the pregnancy, or may have developed after the abortion. If it pre-existed it may have played a rŏle in causation.

Case 1 had suffered much of indigestion since the illness following her first confinement, yet her vomiting was less severe than in Case 2, who had no history of previous gastric trouble.

There has been in neither case any history of physical sign of tuberculosis. Neither case presents a strumous diathesis.

A CASE OF RUPTURE OF THE UTERUS AND VAGINA.[1]

By DR. JALKO-GRINTSEVICH.

RUPTURE of the uterus or vagina, more frequently of both together, belongs to the most unfavorable accidents that may happen during pregnancy, more frequently during the act of parturition. Such accidents usually cause not alone the death of the mother and fœtus, but give rise to the generally groundless accusations against physicians who tended the patient, charging them with carelessness and lack of knowledge of obstetrical manipulations. Although such unfortunate cases are of rare occurrence of late, since obstetric operations became more perfect, nevertheless science cannot ward off or foresee those cases where rupture of the uterus is spontaneous or caused by the attending physician.

The causes which predispose pregnant women to rupture of the uterus are:

1. Diseased weakening of the uterus itself, due to thinning of its serous, fibrous coats or fatty degeneration.

2. Great mental excitement, which causes a sudden contraction, even of a healthy uterus.

3. Great exhaustion or violent movements, traumatism, falls, severe vomiting, and various other mechanical causes directly or indirectly influencing the uterus.

4. A long series of anomalies, to wit: double uterus, contracted pelvis (which, according to Radford,[2] occurs once in eighteen parturitions), extra-uterine pregnancy, all new growths of the ovaries which distend the already distended uterus, etc.; and

5. Awkward manipulations of the accoucheur while extracting the fœtus.

Obstetrical casuistry is rich in literature describing rupture of the uterus during pregnancy, as well as during parturition. I will endeavor to remind the readers of the most striking cases.

H. Cooper[3] had under observation a case of rupture of the uterus occurring at the third month of pregnancy; MacKinley,[4] at the fourth month; Harrison,[5] fifth month; Mitchell,[6] sixth month, where the woman, feeling some pain in her stomach, suddenly expired, being frightened by a flash of lightning, and the uterus, having contracted around the knee of the fœtus, was ruptured. A similar case was reported by Scott,[7] of Bromley. A woman, at the fifth month of pregnancy, was awakened at night with severe pains around the umbilical region, and the autopsy showed a rupture of the fundus of the uterus, through which the fœtus, with the membranes, was protruding into the abdominal cavity. Cases at eight or nine months are rarer. The first who described such cases was Guilleman,[7] after Velpeau.

The frequency of rupture of the uterus is estimated by various authors differently. According to Ingleby,[8] one rupture to 300–400 pregnancies. According to Bluffy,[9] one in 466 pregnancies. Collins[10] has seen 16,414 pregnancies and 34 ruptures—*i. e.*, one rupture in 482 (two recovered, and one even gave birth afterward twice). McClintock Hardy, in 6,634 deliveries, had 9 cases—*i. e.*, one in 737. Ramsbotham[11] reports that, in the Royal Maternity Charity in London during the period of 21 years, there were 48,719 deliveries, with 11 cases of rupture of the uterus or vagina —*i. e.*, one in 4,429. From the statistics collected by Franque,[12] it appears that, in 367,708 deliveries, there were 114 cases of rupture—*i. e.*, one case to 3,225 deliveries.

R. Barnes[13] says that rupture of the uterus during parturition occurs at the time when the head of the

fœtus enters the pelvic cavity; when the pressure upon the upper segment of the vagina is very great, and the uterus, in its attempt to expel the fœtus, distends the ring of the os with such force that either a longitudinal or circular rupture happens.

According to Ingleby,[1] the ruptures are more or less oblique; sometimes the rupture extends around the whole circumference, thus severing the uterus from the vagina. Collins, Moulin, Elkington, Roberton, and many others describe cases of complete severance of the uterus from the vagina. Simpson has seen a case of simultaneous rupture of the uterus and peritoneum following the injection of warm water into the uterine cavity to induce labor. Ruptures of the vagina were minutely described by McClintock[2] and Scanzoni. They may be complete or incomplete. The incomplete happen in either the upper or lower third of the vagina. If the posterior wall of the vagina is ruptured, the fœtus gets into the peritoneum and the bowels protrude. The large size of the body or head of the fœtus may, if accompanied by other complications, be the cause of the rupture, which explains the reason that the majority of ruptures happen in the deliveries of male children.

Fortunately for the physicians, they are rarely present at the time of the accident, for they are mostly called when all is over. Though, according to the opinion of all the authorities, the physician witnessing a rupture, or performing an obstetrical operation, is neither able to prevent the possibility of a rupture of the uterus nor can he foresee, judging by the symptoms alone, the danger of a coming rupture, nevertheless, the public, in such cases, accuses not only the physician who performed the operation, but even him who was merely present at the delivery.

There are many cases on record where physicians were charged in courts of justice with ignorance of obstetrical manipulations, which were supposed to have caused rupture of the uterus. However, in all the reported cases, the medico-legal experts invited by the courts have, in the majority of instances, found them guiltless. I will cite only one instance, which occurred in London in 1860, where a physician was accused that, by awkward and unscientific manipulations, he had caused a complete circular severance of the uterus from the vagina, with a prolapse of the uterus and placenta. However, the committee of experts, consisting of Barnes[3] and Hicks, found him innocent of the charge, and the cause was ascribed to the diseased state of the parturient, and the relaxation and weakness of the uterine tendons, which could not withstand the pressure of the parturition. A similar case is reported by Paget,[4] of Leicester, and many others.

The case of rupture of the uterus which I am going to relate, from my own private practice, may be numbered among those rare cases in obstetrical practice where the physician figures not as a mere witness who merely reports what has already taken place, but as one who had the opportunity to watch and observe, and also take an active part. I submit it as a very instructive case to young fellow-practitioners, solely with the view of giving a true picture of what a predicament one may find himself in.

On the 19th of September, 1889, at noon, two men called upon me and requested me to examine their relative, who was severely injured in a fight, and also to visit his wife, who, thinking that her husband was killed in the affray, was unable to give birth.

Having arrived at the house of the patient, I found there the midwife, Mrs. Grigorieff, who informed me that the bag of water was ruptured early in the day, and the labor pains had ceased since a few hours. Mrs. O., the patient, was forty years old, multipara, and, according to the report of the midwife, her latter deliveries were quite difficult; adding also that Mrs. O, applied to her for the relief of some uterine trouble.

Previous to my arrival many attempts were made by the midwife to extract the child forcibly.

Having examined Mrs. O.,. I found her genitals greatly swollen, of a bluish-red color; a bloody serum mixed with mucus was exuding; pulse very feeble; no pains. On digital examination, oblique position of fœtus and presentation of right arm.

Having waited for quite a long time, I thought it advisable, in view of the dangerous condition of the patient, to deliver artifically. I introduced my hand into the cavity of the uterus and performed podalic version. While extracting the legs, I felt the want of resistance to my pulling; still I continued the operation, extracting the body and easily freeing its arms. My attempts, however, to extract the head, by hands or forceps, were unsuccessful, as the head was high up, and could not be reached, even by the fingers. Having noticed, by the absence of pulsation in the cord and the peeling off of the skin on the back and legs, that the fœtus was dead, and that the parturient was in a precarious condition, with a lowered pulse and bathed in cold sweat, which required immediate relief, and not being able to consult with any other physician, on account of their absence from the city, I decided to decapitate the fœtus. Resorting to this hazardous operation in the absence of any other means of extracting the head, I thought to gain by so doing more freedom of action. But, even after the head was severed from the body, all my attempts to extract were futile, as the head slipped away and was moving freely in the lower region of the abdomen, which led me to the conclusion that the uterus was ruptured, and to extract the fœtus through the birth canal would be impossible.

As to the time of the occurrence of the accident, it may have happened thirty-six hours previous to my arrival, before the bag of waters was ruptured, at the time when the uterus was in a state of its highest tension. This supposition is mainly based upon my observations of the sanious exudation from the genitals and the general collapse; there being no sudden and excruciating pain, which, according to all authorities, accompanies rupture of the uterus, and which I did not notice while performing version; and, finally, the ease with which I extracted the body, not meeting any resistance from the ordinary tight grasp of the uterine walls around the fœtus. A spontaneous rupture of the uterus may have occurred. On account of the parturient being a multipara, having difficult deliveries, suffering with uterine trouble, and therefore the fibres of the uterus may have presented considerable friability and insufficient elasticity; that the fœtus was dead, due to its abnormal presentation; that the head was pressing for a considerable time, and compressed the already degenerated uterine fibres; of the nervous shock she had received at the information of the death of her husband, and the interference of the old woman previous to my arrival—all these were such favorable instances, each of which separately could have caused rupture of the uterus. Although I cannot deny the fact that, notwithstanding the rightly-performed operation of podalic version (sev-

enty-nine times during my fourteen years of professional career), in the state of health of the parturient and the accompanying circumstances, the rupture of the uterus may have occurred during the version.

Having ascertained that I could render no services to the parturient, and also in view of the fact that she herself and all the others objected to any further medical interference, and her state was hopeless; fearing, also, the threats of those surrounding her, I departed, after a six hours' stay, telling them, however, in case they would need my aid, to send for me.

I was not called, and I learned afterward that she died on the second day—*i. e.*, on the 20th of September, at 2 P. M., of gradual exhaustion.

The autopsy was made four days after her death. When the abdominal cavity was opened, the first object in view appeared, the head of the fœtus, lying in front of the uterus, face downward into the cavity of the pelvis, and the occiput upwards; frontal to the left and throat to the right of the hypogastric region. Having carefully removed upwards, it was found, in the true pelvis, at the junction of the uterus and vagina, a transverse rupture of the fundus of the vagina five inches in length. The uterus was found to be ruptured longitudinally two inches long. Other injuries there were none. In the bladder, which was empty, was found coagulated blood.

The diameter of the head of the fœtus: longitudinal, 4½ inches; transverse, 3½.

PHILADELPHIA HOSPITAL.[1]

SERVICE OF ERNEST LAPLACE, M.D.

RADICAL CURE FOR HERNIA.

THE first case I bring before you this morning is one of great importance, and I will request you not to raise any dust, as, in the present day of antiseptic surgery, we are only allowed to operate under the most favorable surroundings, and should not expose the wound unnecessarily. This case will undergo the operation for the radical cure for scrotal hernia. The operation consists in cutting into or upon the sac, investigating matters, and looking for adhesions; reducing the hernia; dissect the sac and put a ligature around its neck; obliterate the sac and treat antiseptically.

What are the dangers connected with this operation? We must think of the epigastric artery, and in this case it is internal to the hernia. We are not going to cut around the ring, but we only want to obliterate the sac at its neck. The sac is a projection of peritoneum, pushed through the ring by a knuckle of the intestine. This is a scrotal hernia which was acquired. A congenital scrotal hernia has no distinct sac, but the intestine goes through the ring into the tunica vaginalis testis. In this case the sac is in front of the tunica vaginalis testis. The acquired cases of hernia are the cases, if there are any, where we should be prudent and cautious in the use of antiseptic measures.

In this case you will find that, contrary to what I have just said, I will not be *anti*septic, and will not use antiseptics, but I will be *a*septic. I will remove all germs, and there being no germs present why use antiseptics? Antisepsis is a stepping-stone to *a*sepsis. That is the reason why Tait decries antiseptics. He is so careful in the preparation of his patient, assistants, and instruments, that there are no germs present, and, therefore, no need of antiseptics.

We have subjected the cotton to be used in this case to the heat in an oven for an hour, and we know that all germs have been killed. The patient has been given a bath, and the parts thoroughly washed with soap and water; then with ether and sublimate. A towel dipped in sublimate has been on the parts all night. All hair has been shaved from the region in which we will operate.

The first point to be done is to reduce the hernia, and have the assistant place his fingers firmly over the inguinal ring—the inguinal canal is virtually destroyed, for the external and internal rings are in opposition. I cut directly over the sac and dissect it out. The great point is to isolate the spermatic cord so as not to include it in the ligature. We are not using carbolic acid or sublimate solution, but water that has been boiled and allowed to become luke warm. I can see this glistening membrane and know it is the sac of peritoneum. I divide all adhesions with my fingers and can outline the membrane as it comes through the ring. Pass a ligature around the neck of the empty sac close to the ring. Be sure that the hernia is wholly reduced, and examine carefully, so as not to include the spermatic duct. It makes little difference if the spermatic veins are ligated, for this is done in the operation for varicocele. I draw the ligature tightly, and simply leave the sac in position, for I think it will be obliterated, owing to the irritation I have produced. I make an opening in the sac for the escape of any secretions that may collect in it.

The wound is thoroughly painted with a solution of iodoform and ether; a drainage tube is put in: a continuous suture, which supports the parts better than the interrupted, is used; and the parts dressed with iodoform and sterilized cotton and a layer of oiled paper is placed over the whole to keep out the dust. There is no reason why the wound should not heal by first intention.

TALIPES EQUINUS.

The next case I bring before you is this little boy, who has an affection called talipes equinus. Like the other forms of club foot, it may be hereditary or acquired. The etiology of the disease is not known. Some forms of club foot are due to an irregular development of the astragalus. We may have talipes varus or valgus, but in those cases where the muscles are shortened or paralyzed, the direct cause is not known. Here is another of those cases where scrupulous precautions are indicated. For ages tenotomy has been performed with the same good results, because we used a good, clean knife, and no germs got into the wound, because, unlike large wounds, it was not exposed to the air. In performing tenotomy, one must be careful not to wound the underlying structures.

Stretch the foot so that the tendon will stand out. Put the tenotome under the tendon, with the edge directed out, allow the tendon to cut itself, and do not remove the knife until the tendon gives a distinct snap. If we did not put a permanent dressing on this foot, the tendency would be to return, for, as tendons are living tissues, granulations occur and fibrous tissue is formed, and the ends unite, and by the contraction of the cicatrix the foot is drawn in the same position. Keep the foot in a flexed condition, and in this way the tendon will be lengthened when healed. Dress the parts antiseptically, and put on a plaster of Paris dressing. In putting on this dressing let me impress the necessity of a good layer of cotton next the skin. Pain is caused if there is not enough cotton, because the parts will swell, and by the pressure cause pain.

ARSENICAL PERIPHERAL NEURITIS.

BARTON records two cases in *The Lancet*. In the first case a woman, aged twenty-three years, gave a history of two months' illness. The attack began with severe occipital headache, lasting two days, and followed by diarrhœa. On the sixth day she was prematurely delivered of a child, which soon died. A few days later the fingers became numb; extending to the hands and wrists; and the next week affecting the toes and the knees. Loss of power followed in the hands and legs; so that in three weeks from the beginning of the attack she could hold nothing in her hands, though she could sit erect and control the sphincters. She had hyperæsthesia of the forearm, thigh and calf muscles; great pain in extending them, and spontaneous pain also, which prevented sleep. Tactile sense and pain were normal; the feet felt cold, and were covered with sweat. Muscle reflexes in arms and legs were lost, but the plantars were normal. The limbs wasted; brown maculæ appeared on the face and legs; the muscles did not react with either current.

The other case was this woman's husband; and his occupation disclosed the source of the disease. He was assistant to a naturalist, and prepared the birds' skins by rubbing into them an arsenical preparation. His symptoms resembled those of his wife.

Oxide of silver was given, in doses of two grains thrice daily, and he rapidly improved. The author draws attention to the importance of examining the urine in cases of peripheral neuritis, for the poisons that are known to be capable of producing this state. The close analogy of these cases to alcoholic and other toxic palsies indicates that the pathological condition is the same—namely, an inflammation of the sheath and probably of the parenchyma of the peripheral nerves.

These cases lead us to remark upon the great importance of a close study of obscure cases. There can be little doubt that, in the hurry of a physician's busy life, many cases are classified as variants from ordinary affections, when closer observation would afford interesting, perhaps startling, revelations. Especially is this the case where the possibilities of poisoning are considered. Dr. Janney said some years ago, as the result of his observations while coroner, that cholera morbus is never fatal to a robust man in this country, and that the cases so recorded in our mortuary reports are really instances of arsenical poisoning.

A good, *modern* work on toxicology should form part of every physician's reading; and once in five years such a work should be purchased, that the practitioner should be ready to detect the symptoms of metallic or organic poisoning, when presented. Not only is arsenical poisoning attributed to cholera morbus, but many other forms of toxicity are overlooked. Every outbreak of lead poisoning which has been detected, has shown that numerous cases were treated previous to the exposure, without being recognized. Trichina cases crop out whenever a single case is reported, and a corresponding decrease takes place in the number of typhoid fevers. Whether tin poisoning ever occurs is doubtful; notwithstanding the oft-repeated attempts to get up a sensation concerning the dangers of canned goods. Lead poisoning is common enough, if the cans are made of tin containing the other metal, especially if the food contains acids; but pure tin is probably free from all noxious qualities. As to the organic poisons, they are less frequently observed. We are not yet sufficiently informed as to the possibilities of danger from the milk of cows that have eaten poisonous plants. The odorous principles of garlic are absorbed, and communicate the peculiar flavor to spring butter; but how far noxious plants can be eaten with impunity by animals and still prove poisonous in the milk, is an open question.

Annotations.

A WRITER in the Cincinnati *Lancet-Clinic* recalls the analyses of quinine pills published in the *Medical News* in 1883, which showed that the highest-priced pills in the market had the smallest amount of quinine in them. It is noteworthy that the influence of this article is still felt, after the lapse of seven years, and that the mention should be made by a physician in Wyoming.

AS yet, no one has progressed sufficiently in the demand for higher medical education to advocate the course now required by the University of Coimbra. Fourteen years' study are exacted: six spent in obtaining an ordinary education, three in a preliminary scientific course, and five in purely medical studies. Now the students complain because the final examination is conducted in Greek!

We would naturally suppose that the product of such an overwhelmingly complete preparation would be something wonderful; but we do not recollect any great discoveries made by Portuguese doctors, nor any other indications of their superiority over the rest of the professional world. On the contrary, the ratio between preparation and performance reminds us of the story about a man who was disinclined to climb a mountain; therefore he concluded to jump over it. He took a run of three miles to gain sufficient impetus; then, after he had got rested, he walked over the mountain, as others did.

Book Reviews.

DISEASES OF THE RECTUM AND ANUS. Their Pathology, Diagnosis, and Treatment. By C. B. KELSEY. Third Edition, rewritten and enlarged. With two chromo-lithographs and 168 illustrations. New York : Wm. Wood & Co., 1890. Cloth, pp. 483.

The first edition of this work was a book which richly repaid the physician for his investment in it. In the present volume may be seen how much the subject has developed in the hands of its author. While some of the cuts are obscure, there are enough good ones to make this the best illustrated work on rectal disease we have seen. The author says that the chapters on stricture and on artificial anus have been entirely rewritten. The modest preface, however, gives but a poor idea of the amount of work which has been expended upon this edition. In every chapter there are evidences of the author's research, and of the judgment matured by experience. The chapter upon hemorrhoids will be found of special interest, as the author gives the results of his later experience with the carbolic injections, and his reasons for abandoning this method of treatment in favor of Henry Smith's clamp and cautery operation.

In No. 3 for 1890 of *Archives of Dermatology and Syphilis*, Prof. J. Doutrelepont, of Bonn, "On Urticaria Pigmentosa," reports a case of that rare disease, beginning in the sixth month of infancy, the patient (a girl) having previously a clean skin. The case came under the observation of Dr. D. when nine years old, and after seven months was, at the request of the parents, discharged uncured. There was no history of syphilis; and itching, an almost constant symptom in previously reported cases, was absent, and in its stead a burning sensation. In positions where the exanthem abated there was no alteration of the skin.

Dr. Ernest Finger, of Vienna ("Syphilis as an Infectious Disease, from the Stand-point of Modern Bacteriology," draws conclusions from analogy, and formulates hypothesis fixing responsibility for certain manifestations on the germ itself, and for certain others on derived products (ptomaines). In this speculative way he attempts to explain immunity, and also non-contagiousness of tertiary products.

Dr. S. Róna, Buda-Pesth, reports a case of measles complicated with inflammation of Cowper's gland.

Dr. S. Laufer, Buda-Pesth, reports a case of erythema multiforme appearing on the fourth day of a typhoid fever attack, in a female, aged twenty-three, in which death occurred on the twenty-first day of the disease. He attributes the skin disease to micrococci.

Prof. J. Doutrelepont makes a supplementary report to a former one of a case of multiple gangrenous skin disease, which he classifies as Zoster gangrænosus hystericus atypicus recidivus universalis. The origin was a prick of a needle under the left thumb nail ; the duration of the disease over five years, during which time Prof. D. closely observed its progress and course, and the eventual cause of death, pulmonary tuberculosis. The present writer might add that for several years there was under his observation a young hysterical girl (the above case was hysterical, and all others thus far reported except one), who, from a slight burn on the back of the left hand, developed similar symptoms, which, up to the time that she passed from his observation, had never crossed the middle line, and had been confined to the arm and thorax.

Dr. Robert Töply ("Venereal Diseases in the Armies") gives statistics from the armies of all nations and establishes the fact that, for all armies, the venereal cases reach from 50 to 100 per 1,000 men yearly, and that, leaving the American War of the Rebellion and the Crimean War out of the calculations this is a greater loss than from wounded in the years embracing the most active campaigns. In certain garrisons the proportion of affected men reaches one-third. The proportion of wounded English in the Crimean War was under one-third per year ; while in all other wars tabulated it reached, in the highest instance, the French War of 1859, only 150 per 1,000, and in the lowest instance, in Bosnia, 1875, 20 per 1,000.

—Samuel Wolfe.

A Case of Locomotor Ataxia Associated with Nuclear Granial Nerve Palsies and with Muscular Atrophies. By FREDERICK PETERSON, M.D. Reprinted from *The Journal of Nervous and Mental Disease.*

Identité de la Dengue et de la Grippe-Influenza. Par Le Docteur JULES ROUVIER. Prix: Un franc. Paris et Beyrout.

Note on Extra-Neural Nervous Disease. By C. H. HUGHES, M.D., St. Louis, Mo. Reprint from *Alienist and Neurologist.*

Circular Insanity. By THEODORE DILLER, M.D., Danville, Pa. Reprint from the *Amer. Jour. Med. Sciences.*

Chorea in the Adult as Seen Among the Insane. Some Observations on the Hereditary Form of Chorea, with the Report of a Case. By THEODORE DILLER, M.D., Danville, Pa. Reprint from the *Amer. Jour. of Med. Sciences.*

The Medical Digest.

LUCIANI reports two cases of facial epithelioma cured by the local use of resorcin.

RISK (*Brit. Med. Jour.*) reports a case of deafness from syphilitic disease which recovered under the use of pilocarpine.

HÆBERLIN mentions a case in which exophthalmic goitre appeared during pregnancy and subsided after the death of the fœtus.

OWEN (*Brit. Med. Jour.*) mentions two cases in which threatened abortion was averted by the use of viburnum prunifolium.

HEER advocates rectal injections of salt water instead of intra-venous transfusion, in cases of severe hemorrhages, post-partum, etc.

DR. MILLER, of Bird-in-Hand, recommends chloralamid as one of the best hypnotics for the insomnia of old persons and nervous females.

IN *Notes on New Remedies* a correspondent claims that succus cinerariæ maritimæ is curing his cataract by causing absorption of the opacity.(?)

FAVRE found antipyrine promptly efficacious in mastering an erysipelas that had resisted ichthyol, corrosive sublimate, strapping, cold, carbolic acid, etc.

BROUNER (*Brit. Med. Jour.*) mentions three cases in which concussion of the eyeball, in patients subject to congenital syphilis, gave rise to interstitial keratitis and peripheral choroiditis

LATE CHILD-BEARING.—Dr. E. F. Parsons, of Thompsonville, Conn., reports the case of a lady who was married at the age of fifty years, and gave birth to a female child after she was fifty-one years old.

WILE pronounces sulphonal an ideal hypnotic for children. In the case of an infant aged eighteen months, sixty grains were given by mistake, with no worse effect than a twenty-four hours' nap, and a cessation of the convulsions.—*N. E. Med. Monthly.*

IN the *British Medical Journal* Capes records the case of a woman who had varicose ulcers on both legs, supposed to be due to tight garters. While returning from her work one day bleeding commenced from the internal saphenous vein, and the woman died before she could be got to her home.

SUBLIMATE PELLETS are generally made with the addition of ammonium chloride, but Bond (*Lancet*) suggests the substitution of sodium chloride for these reasons: 1. With hard water the mercury and soda does not form a milky solution, or throw down a precipitate. 2. The solution is neutral and not acid; besides the sodium salt is a constituent of the body fluids.

TROPICAL DIARRHŒA has been usually treated by a diet of milk, but Neve (*Lancet*) records a case in which, after milk had been given for seven weeks with no improvement in the symptoms, the diet was changed to meat, with toast and weak tea. The day the change was made the diarrhœa stopped, and did not return.

ARISTOL has been employed by Eichhoff in the treatment of varicose ulcer with eczema, lupus-exedens, psoriasis, ring-worm, sluggish ulcers, seborrhœic eczema, and congenital syphilitic ulcers. In all of these aristol proved superior to the applications previously made. In soft chancre it did not do as well as iodoform.

HYDRONAPHTHOL is recommended by Clarke (*Practitioner*) in typhoid fever, green diarrhœa of infants, dysentery, and ordinary diarrhœa. He gives two to three grains every two hours. In flatulent dyspepsia and dilatation of the stomach it was of little use. Nausea was caused in some cases, and two out of five of his typhoid cases were severe and prolonged.

HYPNOTISM AND THE CHURCH. [Extract].—A few days ago, an eminent Jesuit priest, Father Lemoigne, by permission of the Archbishop of Paris, spoke as follows from the pulpit of St. Merry, and his words are worthy of preservation.

"To hypnotise a person in order to avoid suffering in the course of a painful surgical operation, is permitted by the Church.

"To employ hypnotism by suggestion, to make an invalid walk who has lost the power of motion, to enable an invalid to eat or to recover the use of his voice, temporarily lost, is permitted by the Church.

"To hypnotise a sick person to alleviate or cure him of disease, to retard the return of nervous crises, which are so common among women and not unknown among men, is permitted by the Church."

The above directions, from the mouth of a prominent clergyman, form an excellent guide for hypnotic applications in therapeutics.

—*La Reforma Medica* (Mexico).

RICKETTS (*Lancet-Clinic*) reported a case of trephining for traumatic epilepsy. Some suppuration followed the operation. The description does not state whether any lesions were found within the skull; and the history renders it doubtful if any operation should have been done; as the man had been a masturbator, his father a drunkard, and his mother hysterical. Five weeks after the operation, the convulsions were less frequent; the last week he had six, whereas before the operation he had had as many as eight per day.

SIR JAMES SAWYER (*Lancet*) recommends ethereal tinctures for use when it is desired to produce a local effect on the skin. Three obstacles to absorption exist; epidermis, the sebaceous secretion, and the insolubility of the drug. Ether has great endosmotic capacity; it probably possesses in a high degree what has been called "diffusion power." It is a powerful solvent for many active drugs, and dissolves the sebum readily. Capsicum, belladonna, iodine and menthol are recommended for local use in ethereal solutions. Ethereal tincture of menthol, one drachm to the fluidounce, is an efficient remedy for superficial neuralgic pains. He applies it with a glass brush.

HOW TO BOIL AN EGG.—I believe that ninety per cent. of the eggs are spoiled by the cooking. A physician orders a soft-boiled egg for his patient; the cook places in the boiling water the egg, and allows it to *boil* for three minutes, takes it out, and thinks she has a soft-boiled egg; but she hasn't. She has an egg cooked hard on the outside and still raw in the middle. Now, if she had first boiled the water, then removed the kettle and stood it on a piece of old woollen cloth, so that the heat would not escape too rapidly, then placed the egg in the water, and allowed it to remain about *six* minutes, she would have an egg evenly and softly cooked throughout, and a very elegant one at that.—*Medical World.*

GEO. R. FOWLER suggests the following as an infants' food:

Put four tablespoonfuls of rice into three pints of water, and boil half an hour; then set aside on back of range to simmer during the day, water being occasionally added by the cook to maintain the original three pints. At night strain through a colander and place on ice. When cold a paste is formed. Three tablespoonfuls of this paste are added to each nursing-bottle (half pint) of milk, and fed during the next day, a fresh supply of rice-paste being under way in the meantime. Should there be constipation, I use farina, prepared in the same way and used in the same proportion. Rice is astringent, farina laxative.

—*Med. Record.*

SULPHONAL.—Field (*New England Med. Monthly*) gives the following recommendations as to sulphonal. The proper adult dose is 15 grains, to be reduced to 12 or 10 after a few days.

The dose should be taked about two hours before the hour for retiring.

The drug should be given in fine powder dry on the tongue, in capsule, or simply wetted on a spoon; never in tablet or suspension.

After taking the dose the patient may read, smoke, walk, etc., as he likes; but must do nothing to cause mental or nervous excitement.

So many grains of sulphonal will buy so many hours' sleep; at first light, but becoming gradually deeper. If the patient is awakened before the time

has elapsed, the effects of the drug will still be manifested for the remaining period by dizziness, etc.

When a minimum effective dose has been determined it may be continued indefinitely.

The point most dwelt upon is the almost mathematical certainty of the effect as compared to the size of the dose.

Catheter Fever.—In failing to recognize a septic cause for the fever which occasionally accompanies catheterism, and referring it to some occult morbid condition of the nervous system, I cannot help observing that the same kind of explanation was advanced, up to a few years ago, as explaining the rigors and fever following the use of instruments for urethral stricture, until I demonstrated, by a series of operations that these phenomena were due to the absorption of some products of the urine, probably of the nature of alkaloids. On this being recognized and provided against, as it now is in most operations on the urethra, the occurrence of such complications, often attended with considerable risk, has been largely diminished, if not entirely prevented, in the practice of most surgeons.—Harrison, *Med. Press.*

Rhubarb as a Cause of Hæmaturia.—It is well-known that the ingestion of rhubarb, celery, and sundry other edible vegetables conduces to the elimination of oxalates in the urine, but the fact has not had any importance other than a physiological curiosity. It is, however, possible that the passage along the genito urinary canal of these prickly crystals may, in certain persons, determine serious irritation, even running on to hæmaturia. Such, at least, is the conclusion of a correspondent who remarked on three occasions that more or less violent attacks of hæmaturia followed a meal comprising stewed rhubarb, in his son. The family was a gouty one, and this may account for the abnormal irritability of the kidneys, for hæmaturia is, fortunately, not a usual, or even a common sequel to a feast off rhubarb.—*Hosp. Gazette.*

Bacteriology of Typhoid Suppurations.—A large majority of authors deny any pyogenic properties of the typhoid bacillus, and ascribe the complications to a "mixed infection" of the patient's system with the specific microbe of enteric fever, and various pyogenic bacteria. Of late, however, a series of cases was reported (by Fraenkel, Kocher, Favel, Weichselbaum, Roux, Vinay, Valentini, and Ebermaier), in which a most careful bacterioscopic examination of typhoid abscess failed to reveal the presence of any microbes beyond the typhoid rods. The question naturally arising, "whether the specific typhoid microbe can give rise to suppurative inflammation, or not," Dr. Orloff has undertaken very extensive course of inoculation experiments on rabbits and dogs, which enables him to lay down the following propositions:

1. Injections of "pure cultures" of the typhoid micro-organism into tissues give rise to local inflammation, with round-cellular infiltration.

2. When injected into joints, the microbes cause the appearance of a sero-purulent, frequently thick mucoid effusion.

3. When introduced under the periosteum or into muscles, the bacilli produce round cellular infiltration (chiefly in interstitial connective tissue), followed by partial sloughing, with disintegration or (more rarely) suppuration.

4. A similar infiltration is also observed after injections of the cultures into the testicle, fractured bones, and inflamed subcutaneous cellular tissue.

5. A subcutaneous injection of the bacilli (in dogs) brings about the development of abscess.

6. The injection into a healthy pleural cavity gives negative results.

7. Injections of sterilized (dead) cultures of the typhoid rods are followed by the same morbid phenomena as described *sub* 1, though in a less intense degree.

8. The fact justifies the supposition that phlogogenic and pyogenic properties of the microbes are dependant—at least, to a considerable extent—upon some chemical substances (such as Brieger's typhotoxin) developing in the cultures in connection with their vital process.

9. In such cases of suppuration complicating or following enteric fever, where the pus proves to contain the typhoid bacilli alone, the morbid process (suppuration) must be attributed to the latter, and not to Brieger's "mixed infection" (*vide supra*).

10. In mixed cultures, the typhoid microbe does not appear to produce any influence on the vitality of the staphylococcus pyogenes aureus.

—*Provincial Med. Jour.*

Gargling has been pronounced by Mackenzie comparatively useless for affections of parts posterior to the anterior faucial pillars. Swain, in the *Medical Record*, concludes that: 1. Gargles, rightly used, reach the larynx, and at the same time can be brought into contact with all the accessible overlying parts of the upper air passages. 2. The method advocated leads surely and easily to the above results. 3. The radically different opinions of authors as regards the value of gargles have led to the neglect of a valuable adjuvant in the treatment of affections of the upper air passages.

The method advocated is that of Hagen. The mouth is a little more than half filled with the gargle; the head is bent back, the mouth opened wide, and a complete movement of swallowing made, not allowing the mouth to close. This movement of swallowing must be complete, though little or none of the fluid will reach the stomach if the mouth remain open. The air is then allowed to gurgle through the liquid as long as possible; then placing the tip of the tongue against the upper incisors, a quick nod allows the fluid to be ejected through the nose.

The advantages of this method are its simplicity, the thorough cleansing of the mouth and nose, and its scope. To facilitate the operation, the thumb may be placed on the lower incisiors to keep the mouth open.

Cooling Salves.—Unna (*Ther. Monats.*) says: "Cooling salves are mixtures of fats and water, which, by continuous evaporation, withdraw heat from the skin. They are useful substitutes for the ordinary ointments. When anhydrous lanoline is mixed with fat, mixtures result that are less tenacious of water than lanoline alone, and permit evaporation."

Following are Unna's formulas:

Ungt. Refrigerans:

R.—Lanolini anhydrici 10.0
Adipis benzoin 20.0
Aquæ rosarum 30.0
Use as a cold cream.

Ungt. Refrigerans Aquæ Calcis:

R.—Lanolini andydrici 10.0
Adipis benzoin 20.0
Aquæ calcis 30.0
Use as ointment base for application to burns.

Ungt. Refrigerans Plumbi Subacetici :

R.—Lanolini anhydrici 10.0
Adipis benzoin 20.0
Liq. plumbi subacetici 30.0
Use same as Goulard's cerate.

Ungt. Refrigerans Zinci :

R.—Lanolini anhydrici 10.0
Ungt. zinci benzoin 20.0
Aquæ rosarum 30.0
Use in place of zinc ointment where simple fats are not tolerated.

Ungt. Refrigerans Pomadinum :

R.—Lanolini anhydrici 10.0
Ungt. pomadini 20.0
Aquæ destill 30.0
Use in place of ordinary pomade bases, and, if preferred, on occasion employ lime water instead of water.

Cremor Refrigerans :

R.—Lanolini anhydrici 10.0
Adipis benzoin 20.0
Aquæ rosarum 60.0

Cremor Refrigerans Aquæ Calcis :

R.—Lanolini anhydrici 10.0
Adipis benzoin 20.0
Aquæ calcis 60.0

Cremor Refrigerans Plumbi Subacetici :

R.—Lanolini anhydrici 10.0
Adipis benzoin 20.0
Liq. plumbi subacet 60.0

All the preceding formulas are intended for extemporaneous use, and the preparations should not be made for storing.—*Notes on New Remedies.*

Treatment of Obstructive Dysmenorrhœa.[1] (Thomas More Madden, M.D., F.R.C.S.Ed.)—In the recognition of obstruction from cervical stenosis as the chief cause of dysmenorrhœa, will be found the key to pathology and successful treatment of this condition in the great majority of cases. Thus in my hospital practice during the past twenty years, nearly eleven per cent. of sterility similarly caused have come under observation in a total of nine thousand gynecological cases. Of all the ailments of female existence, few give rise to more persistent suffering, or produce more disastrous effects on the general health, and even on the cerebro-nervous system, or on the moral constitution of the patient, than does well-marked obstructive dysmenorrhœa. The latter consequence is more especially evident in many cases of alcoholism, which in women may very frequently be dated from their first painful menstrual period, for the relief of which stimulants are too often improperly administered, and repeated in increasing doses, until finally, in many cases, the victim of dysmenorrhœal alcoholism becomes a habitual, and, perhaps, an incurable drunkard.

It is not my purpose here to refer to the successive improvements which have since been effected in the methods of carrying out the gradual dilatation of the cervical canal, since the introduction into practice by Simpson and Swan of sponge tents, or laminaria bougies for this purpose. No greater improvement has occurred in our branch of surgery than the replacement of these oftentimes unsatisfactory, possibly hazardous, or even fatal, and always painful procedures by the more effective means now at our disposal for the rapid expansion of this canal. Of these, perhaps, the best known and most generally employed are either Hegar's, Duke's, or Lawson Tait's dilators. I now desire to call attention to another instrument which I have designed for the same purpose, and which, I venture to hope, may be found to supply a want still recognized by the gynecologists—namely, that of a reliable and effective means of securing the rapid and permanent dilatation of the cervical canal in the treatment of stenosis, giving rise to the morbid conditions now under consideration. This instrument differs from other dilators in several respects, and, above all, in one which I consider most important—viz., in producing expansion of the canal from within outward—in other words, in imitating the natural process of expansion from the uterine cavity downward to the os uteri : whereas most other dilators, such as Hegar's, etc., act in the opposite direction. In my own hands the utility of this instrument, the expansion effected by which may be measured by the affixed index, has been fully tested in a very large number of cases of sterility and dysmenorrhœa in hospital and private practice. I may add that my dilator, which does not occupy more room than the ordinary sound when introduced, may also be used with advantage for the dilatation of the female uthera in many cases in which this procedure is indicated. This instrument has been carefully made in accordance with my directions by Messrs. Arnold and Sons, West Smithfield, London.

[1] Abstract of a paper to be read before the Berlin Congress. From advance sheets.

Summer Disturbances of Children.—There are times when it is desirable to change the food of the babies the same as we need to change the bill of fare upon our table. We must not forget that the palates of the little ones are to be consulted ; that "variety is the spice of diet" may be applied, in a mild way, even to the babies. The food that agrees with the baby to-day, or this week, or this month, may need changing next month. I present the following conclusions :

1. During the heated term keep the baby cool, but not too cool ; just cool enough. Uniformity should be the ruling thought. Babies do not enjoy extremes of anything.

2. The proper regulation of the diet, the proper degree of sleep, the proper uniform temperature, pure air, and the proper relief of thirst will enable every infant to weather the tide of the hot sultry days of mid-summer.

3. The severe intestinal diseases, and the one which is the very acmé of infantile danger—cholera infantum—may be passed serenely by if we impress upon the mothers the fact that the very first variation from the proper digestion should be corrected by the family physician, and not by the "busy-body" neighbors.

4. The mother should be impressed with the fact that the opinion of the physician is of as much importance in the matter of food as though medicine were to be administered ; in fact, it is of paramount importance, in that food is life to the child.

5. Experimentation at all times is risky, and particularly so when dealing with infants, and doubly so when the experiments are not conducted by an expert experimentalist. In the correction of disturbed digestion we should aid nature in getting rid of undigested and indigestible materials.

6. We should bear in mind the antiseptic thought.

7. We should see to it that less diet and a more digestible diet be brought into requisition.

8. During the entire period of infantile life we should protect the abdominal region against possi-

ble chilling by the wearing of a light woolen belly-bandage.

9. Relieve the thirst by good, pure water, instead of the breast or the nursing-bottle.

10. Proper rest and tranquilization of the little one is desired; above all things let it be kept away, if possible, from the heated body of the nurse or mother, who, in addition to elevating the temperature of the child by contact with her own personality, will more than likely alter each filling up with milk, proceed in an affectionate way to trot it up and down, from side to side, and in a generally gymnastic way exercise her motherly muscles in giving the little one the soothing effect of thorough agitation, resulting in that which we find at every street corner — the "milk shake." More than likely the baby will reject the particular milk shake made in that particular way, but the result is not always so fortunate. It is far better for the little one to be placed upon a recliner the bulk of the time, in a manner favorable to sleep and digestion.

11. Religious regard for cleanliness of all food utensils, refrigerators, and nursing-bottles should be insisted upon. Not less than three or four of the simplest form of bottles should be always on hand. The nursing nipples should be plain, black rubber. The handy but filthy tubular affair should be condemned *in toto*.—Love, *Memphis Med. Jour.*

THE HEAT AND ITS EFFECTS.—The heat of the last two weeks has been remarkable as occurring so early in the season, it being very rare, indeed, for fatal sunstrokes to occur in the first summer month. More than a score have already taken place in this city, while the news of the daily press informs us of a similar mortality in other cities and towns; while even those who live in the country are not exempt from the fatal effects of the sun.

Reports of sunstroke are usually of the heat-effects on adults, while the direct and indirect effects on the infant population are many times as great. Too often their main nutrient, milk, has become tainted or poisoned from the absorption of germs and gases, making it a dangerous article of food and productive of summer enteritis, or other trouble that leads to a fatal termination.

At this time of the year it is a good plan to have all milk sterilized as soon as possible. This is a very simple process, and consists in putting the milk in a clean bottle, loosely corking with a clean, new cork, and then placing the bottle in a vessel of water and heating it slowly to the boiling point, this temperature being continued for forty-five minutes; then tightly cork the bottle and set it in a cool place until needed for use.

The nutrient properties of the milk are not destroyed, or even weakened, by this process; but, for most persons, it is more easily digested and is more nourishing.

Babies, children and adults, in hot weather, should live as much as possible in the shade, where there is the freest possible circulation of pure air. Long and frequent cool baths for infants are very conducive to their health and comfort. There is nothing like a long, cool bath to relieve the discomfort of prickly or summer heat; following this with a little anointing of the creases of the skin with cold cream, vaseline, or fresh lard.

In case of looseness of the bowels, a few doses of the ordinary chalk mixture will usually furnish the desired relief. This should be given in tablespoonful doses, and after every stool. Where there is a weakening of vitality, with very great propriety and advantage, teaspoonful doses of maltine may be added to the sterilized milk; the diastatic power of maltine being capable of rendering soluble and digestible any starchy food that may be in the stomach. Starch foods, such as Irish potatoes and breads, have often been regarded as the immediate and irritating cause of infantile enteric disorders. In part this may be true; and yet these starch foods were the very ones the lacteals and absorbents were crying for, and needed to stay the waste that was going on with fatal rapidity.

Right here the inestimable value of maltine, with its diastatic solvent properties, is quickly made manifest in changing the character of the discharges, and causing an irritant factor to become one of nutrition; given in sterilized milk, the benefit of both is obtained.

In the city it is a good thing, in every possible case, to send the mother and infant out to the parks and suburbs for one, two, or three hours after sundown. The car-ride is easy; while a shawl or other garment spread on the grass will afford a genuine relief from the mother's lap or cradle.

A little instruction from the family physician to his patrons in these simples may be the means of saving many valuable lives; nor should the physician take it for granted that his clients are informed in such matters, for very intelligent people sometimes are ignorant of the plainest hygienic rules. This is especially the case in regard to the care of very young children. We recently saw an illustration of this in a very intelligent appearing mother, who did not even know how to hold her infant in positions of comfort to the babe and ease to herself. Even in such matters as this the doctor may give wholesome advice.

—*Lancet-Clinic.*

FRENCH NOTES.

BY A. E. ROUSSEL, M.D.

THE USE OF ICE IN THE SWEATS OF PHTHISIS.—Rosenbach recommends in the nocturnal sweats of phthisis a singular method which will hardly be accepted by the profession. This method consists of the application of a rubber bag of ice over the abdomen, which is allowed to remain in position several hours. Patients support this treatment very well, even when they present the usual evening exacerbation of fever. This method succeeds in cases where atropia has failed, as well as where the salicylate of sodium, finely pulverized, has been applied over the entire surface of the body.—*La Médecine Moderne.*

THE ADMINISTRATION OF THE IODIDES TO SCROFULOUS CHILDREN.—Iodine and iodoform give better results than in combination with the alkaline salts.

Tincture of Iodine.—For little children, one drop a day, diluted in a small quantity of broth.

Besnier prescribes iodoform in the following combination, which may be continued for a long time:

R.—Iodoform ..... 0 gr. 10.
Honey ..... 120 gr.

The above represents 0 gr. 005 of iodoform to the teaspoonful.

—*Le Bulletin Médical.*

MIXTURE FOR DENTAL CARIES AND ITS ATTENDING PAINS.—

R.—Chloroform ..... 5 grammes.
Laudanum of Sydenham ..... 2 "
Tincture of benzoin..... 10 "

M.—Mix in a glass-stoppered bottle. Apply on cotton to cavity of tooth.

—*Le Bulletin Médical.*

MIXTURE FOR EARACHE.—

R.—Camphorated chloral .... 5 grammes.
Glycerine ..... 30 "
Oil of sweet almonds ..... 10 "
M.—Apply with absorbent cotton.

Gentle friction may also be used on the outside; the pain disappears as if by magic.

THE USE OF MENTHOL IN CORYZA.—

R.—Powdered menthol ..... 0 gr. 20.
Hydrochlorate of cocaine ..... 0 " 10.
Powdered boric acid ..... 10 " 00.
Mix.

R.—Powdered menthol ..... 0 gr. 20.
" coffee ..... 10 " 0.
Mix. Snuff.

—*Journal de Médecine.*

THE NUTRITIVE VALUE OF BOILED MILK.—E. T. Vassilieff performed a series of experiments on six healthy adults, aged from eighteen to twenty-three years, for the purpose of comparing the relative digestibility with raw milk. Each experiment lasted six days. During the first three days the subject took raw milk alone; during the next three days boiled milk was administered. The quantity of milk each day varied from one thousand eight hundred and fifty to four thousand two hundred cubic centimeters. The author arrived at the following conclusions:

1. The assimilation of nitrogenized substances of milk is greater if the milk is not boiled. The average quantity of non-assimilated nitrogenous substances is from 6.42 to 7.62 per cent. in raw milk, and from 7.76 to 8 79 per cent. in boiled milk.

2. The same rate holds good as regards the fats. In raw milk the proportion of fatty acids non-assimilated is from 2.88 to 4.85 per cent., while, on the contrary, in boiled milk we have from 4.53 to 6.99.

3. Consequently, the nutritive value of boiled milk is inferior to that of raw milk.

—*Bulletin de Thérapeutique.*

NOTE.—The above experiments corroborate those made by Drs. N. A. Randolph and A. E. Roussel (Proceedings of the Academy of Natural Sciences, April 29, 1884), when "artificial digestions showed that milk was more readily digested when raw than when boiled. This was further confirmed by a comparative examination and weighing in over fifty cases of the contents of the stomach, after raw and boiled milk had been, in different individuals, undergoing actual gastric digestion. In these cases, the residue found in the stomachs of those persons receiving boiled milk was greater than the similar residue found in the stomachs when raw milk had been undergoing digestion for the same length of time."

IN THE OFFICE OF THE WRONG SPECIALIST.—A physician whose specialty was skin diseases, one day saw a patient enter his office. "Strip off you clothes!" commanded the physician. "But, doctor!" expostulated the patient. "No buts!" exclaimed the doctor, who was quick tempered, "do as I bid you." The patient doffed his clothes and stood naked before the dermatologist, who, examining him closely, remarked: "My good, sir, I can detect no affection of the skin in your case." The patient smiled, and replied: "True, doctor. I came to consult you in regard to my eyes."—*Cincinnati Lancet Clinic.*

Medical News and Miscellany.

DR. GEORGE E. SHOEMAKER is enjoying life at Eagle's Mere.

DR. KLAPP, a prominent Philadelphia physician, is recreating at Cape May.

DR. S. RUSH KETCHAM makes frequent visits to the Chalfonte, Atlantic City.

DR. AND MRS. LOUIS STARR have left Devon Inn and are gone to Avon Inn, N. J.

DR. J. H. REEVES is spending a few weeks at Lake Placid, in the Adirondacks.

DR. AND MRS. N. H. TOWNSEND are spending two weeks at the Stockton, Cape May.

DR. D. W. SHELLY and family, of Ambler, Pa., are at the Richmond, Atlantic City.

X. C. SCOTT recommends iodoform ether as a local application in diphtheria.—*Med. Mirror.*

DR. A. E. ROUSSEL spends from Saturday to Monday of each week, with his family, at Cape May.

DR. MEEKHEIN, a Hindoo oculist, of Boston, was married to Miss Bella Law, of Altoona, last week.

DR. HARRY GODEY is staying at the Tyn-y-Coed, Campobillo, the fashionable resort of the Main Coast.

DR. JOSEPH BERENS, of Philadelphia, is at the Windsor Hotel, Atlantic City, accompanied by his wife.

SINCE 1866 the University of France has conferred 202 degrees on women, 35 receiving the doctor of medicine diploma.

DR. WALTER M. JAMES, a Philadelphia physician, after a pleasant stay at the Chalfonte, Atlantic City, has returned home.

FIFTY physicians sailed last week for Hamburg, on the steamer Augusta Victoria; they will attend the Congress at Berlin.

SMALL-POX is ravaging the villages between Monsonroy and Zagazig, Egypt, and the populations are being almost decimated.

DR. H. G. MCGONIGLE is under arrest, charged with complicity in the recent malpractice case in which Annie Goodwin died.

DR. JOHN D. GRISCOM died at his residence at Haverford College on Wednesday of last week; he was eighty-one years of age.

AMMINOL gas is recommended by Klein as the best agent for rendering sewage innocuous. It deodorizes and sterilizes in about an hour.

LEPROSY was introduced on Anticosti Island by several families infected with the disease moving there from Caraquet, New Brunswick.

MRS. ADOIN WUCHTER, of White Hall, Pa., has not eaten food for one hundred and twenty days; she is suffering from cancer of the pharynx.

J. J. LAWRENCE, A.M., M.D., of St. Louis, is at the White Sulphur for the summer. He is editor and proprietor of the *Medical Brief of England and America.*

THE first of the "Health Talks" was held Wednesday evening, at 1229 Chestnut street, by Dr. A. Victoria Scott, upon "First Aid to the Injured."

DR. BUNTING, of East Mauch Chunk, a retired physician, with his sister, Mrs. M. B. Wolff, of Philadelphia, is spending the season at the Clifton, Asbury Park.

THE evil effects of tobacco may be avoided by introducing into the pipe or cigar holder a piece of cotton wool steeped in a five to ten per cent. solution of pyrogallic acid.

A BILL has been introduced by Senator Evarts, directing the Secretary of the Treasury to pay to Dr. Mary Walker ten thousand dollars, to re-imburse her for her services as an assistant-surgeon during the late war.

SOMEWHERE in the Arabian Nights is the description of a mechanical bird that sang sweetly, but only one song. The proposition to phonograph the song of real birds puts the Arabian idea into better shape than the original.

DR. E. SALMON, United States Veterinary Inspector, and Inspectors Drs. W. H. Wray, A. D. Melorn, and J. T. Ryder, have sailed for Europe to make arrangements for the examination of cattle as they are landed from American ports.

THE National Women's Health Association of America was organized last week, with Dr. Caroline Dodson as President; its object is to bring the medical profession into closer relation with the laity by the discussion of health topics.

DR. MACAN, of Dublin, married a Mrs. Lynch, thinking her to be a wealthy American widow; whereas she was the deserted wife of a laborer. The latter turned up and sued the doctor for damages, but the jury awarded him one farthing.

THE authorities of Upper Manche, in France, thinking that certain maladies are propagated by milk, have introduced an act which authorizes the health officers to demand of the diarymen a list of their customers, that the truth of these reports may be ascertained.

AFTER an illness of two months, Dr. Jacob Roberts died July 20, at his residence, 2033 Green street. The deceased received a stroke of paralysis at that time. He was in his fifty-fourth year. The doctor, a few years ago, was medical examiner for a number of insurance beneficial societies.

"OH, mommer, mommer!" yelled a little darkey, as he saw the militia on the way to camp to-day; "what's them sojers?" "Sojers, chile?" exclaimed the mother; "what you talkin' 'bout? Dem ain't sojers; dem's de District malaria."

—*Washington Star.*

THE beauties of proprietary journalism are graphically illustrated by those two valuable journals, *Merck's Bulletin* and Lehn & Fink's *Notes on New Remedies*. Merck's journal has glowing accounts of the wonderful effects produced by orexin and pyoctanin; while L. & F.'s paper discredits them altogether. The latter, however, finds the dawn of a better day, the promise of the "good time coming," in thiol and its compounds. It is hardly necessary to add that Merck sells the articles he praises, and L. & F. deal in thiol.

THE VALE OF CASHMERE is not quite as nice in reality as it is in poetry. The people are filthy; parasitic skin diseases are common, as well as intestinal worms. The climate is very hot in summer and very cold in winter. Malaria, rheumatism, and pneumonia are common. Leprosy is rife; and the great scourge is syphilis.

RUSSIA is endeavoring to stamp out syphilis. In each district a special doctor is appointed to look after this disease exclusively, treat it, and enforce sanitary precautions. Special travelling dispensaries are provided, to bring medical aid to the sufferers, and pecuniary aid is given to the families of syphilitics who are confined to the hospitals.

THE Philadelphia Lying-in Charity and Nurse School, S. W. corner Eleventh and Cherry streets, is now open for the reception of patients and for the admission of pupils to the nurse class. During the month of June a number of women were confined, whose temperatures, in every case, ran a normal course up to the time of their discharge.

THE *N. E. Med. Monthly* says, editorially, that there are not twenty medical women in New England today who are making a living by the practice of medicine.

This may be true; but there are more than that number in Philadelphia who are making a fair living by the useful and honorable practice of medicine.

DURING May 146 persons were treated at the Pasteur Institute, Paris. Of these 37 had been bitten by animals whose rabidity had been proved experimentally; 91 by animals pronounced rabid after an examination by veterinarians; 18 bitten by dogs suspected of being rabid. The wounds were from dogs in 137 cases, from cats in 8, and once from a man.

A BILL has been reported to the French Parliament which prohibits foreign physicians practising medicine in France unless they have received the degree of a French faculty. No person can practise dentistry unless he has the physician's diploma or a special diploma as dentist, issued by the French government after a course of study and an examination.

A MOSLEM woman went to Illinois to have her throat examined, but refused to let the doctor use the iron tongue presser, on the ground that in Ramadan it is forbidden to let anything "pass one's lips." She yield only when he had proved to her that the instrument contained absolutely no nourishment, but she was as adamant when he proposed to spray her throat with medicated water.

PROF. P. D. KEYSER, Dean of the Medico-Chirurgical College and member of the Board of Health of this city, sailed, July 19, for Europe, to attend the Tenth International Medical Congress. At the same time he is delegated by the Mayor to examine into the matter of the disposal of the garbage and such matters in large cities, which has got to be a question of great moment at this time.

A DREADFUL TOOTHACHE.—Men will do almost anything when suffering from toothache. M. X. was one day attacked on a railroad train, and suffered the wildest tortures. "Ah!" cried he to one of his friends who was traveling with him, "if I only had a piece of cotton for my tooth; but, unfortunately —" here he uttered a cry of joy. "Saved! saved!" and pulled some cotton from his neighbor's ear.

DR. THOMPSON, of Northampton, Mass., died on the 11th of July, and his sanitarium has been closed.

WE are informed that the item relating to Richmond, Va., in a recent issue, was not wholly accurate. She has a free city dispensary, but no city hospital.

THE steamship "Da Bourgogne," which arrived last Saturday, had a case of small-pox on board; as he was the cabin steward, all the passengers were vaccinated.

DR. H. P. WHARTON and wife sailed for Boston yesterday, on the steamship "Indian," the new steamer of the Boston Steamship Company's line. Dr. Donnellan also sailed for the same place.

THE Board of Health of Norristown has received a report from Dr. Charles Cresson, in which he says that the water supply of the town is polluted by cesspool drainage, and is utterly unfit for household use.

DR. W. W. POTTER, in the New York *Obstetrical Journal* for July, speaks of the Woman's Hospital, of Brooklyn, as Dr. May A. Dixon-Jones' private hospital. This is a mistake, as it is an incorporated public hospital.

THE proposal to open the hospital appointments of England to Scotch and Irish graduates, has been rejected by a large majority. Privileges seem good in English eyes, and English hands do not willingly loosen their grasp on any good things that once find their way into them.

THE Omaha Medical Society has appointed a committee to prosecute unqualified practitioners; of whom the city is said to be full. One effect of the registry laws of various States is to drive these persons out into unprotected States, and this has the effect of compelling these to enact similar laws.

A CASE of posthumous labor occurred at Mantua. A woman died in catalepsy; was placed in the coffin, and next morning found horribly contracted, and between the knees lay a new born child, dead. The physicians who investigated the case declare that the woman was certainly dead before the child was born.

DURING May the principal causes of death in the city of Brussels, Belgium, were: Phthisis, 47; bronchitis and pneumonia, 38; enteritis, 32; tubercular meningitis, 26; apoplexy, 22; convulsions, 21; heart disease, 21: old age, 11; suicide, 9; total from all causes, 328. Annual mortality at this rate, 21.6 per 1,000. This does not include 29 deaths of strangers.
—*Jour. de Med.*

ESTABLISHED physicians, encourage young doctors by telling how you yourself once took measles for scarlatina. Don't walk around with a profundity and overwhelmingness of manner, as though you were one of the eternal decrees. And if you have nothing to say that is encouraging, compress your lips, put your hand over your mouth and keep still.
—Rev. T. De Witt Talmage.

MAYOR EDMUNDS, editor of the Cape May *Wave*, published an item in which it was stated that a woman had been overdosed with morphine by Drs. Marcy and McCray, and her life was only saved by the arduous efforts of a homœopathist. Dr. Marcy's son gave the mayor a cowhiding.

Public functionaries ought to know enough of law to prevent their publishing statements that are libellous.

Seldom, indeed, have we experienced such a shock as we received to-day, when in that exponent of the highest culture of the age, the *Boston Medical and Surgical Journal*, we read these words: "Since finishing this article, I have visited my *two last* cases." Has the bean crop proved a failure, or is the blood of the Puritans so diluted with later importations that it can no longer prompt the writing of good English?

WHAT wonderful things occur in America. The *Hospital Gazette* says that in America women doctors are allowed to wear men's clothes, and adds: "We cannot say how many other lady doctors (besides Mary Walker) have thrown aside women's attire in favor of that of men." We can supply this hiatus in the knowledge of our bright contemporary by informing him that not one of our female physicians has followed Mary's example.

IN most cases inebriety means bankruptcy of physical and mental strength, and an effort to conceal it by the narcotic action of alcohol. The natural and acquired limitations of health have been exceeded, and weakness and pain follow. Alcohol covers this up by numbing and paralyzing the protests of the exhausted nerves. A new disease comes on, of inebriety, and a profound paralysis of the entire nervous system follows.—*Jour. of Inebriety.*

THE New York Medical Practice Law, approved June 4, contains the following important provisions:

It reaffirms the State's rights to regulate the qualifications of practitioners of medicine.

It requires a satisfactory preliminary education as a condition to matriculation.

It provides a definite and uniform standard of examinations for graduates.

It divorces medical teaching from the licensing power.

It compels three years' attendance at the medical colleges.—*Jour. Am. Med. Asso.*

THE managers of the Kensington Hospital for Women, Diamond street, opposite Norris Square, are looking for a site upon which to build a new hospital next fall. Efforts are being made to raise $20,000, and $10,000 has already been subscribed. The hospital was organized in 1884 for treatment of women only. It was begun with two beds, but the number has been increased to thirteen.

During the past year one hundred and fifty women were treated. It is the intention to secure an endowment of $100,000 for the institution. The work at present is being carried on in two adjoining dwellings.

THE TYPE OF IDEAL BEAUTY.—

R.—Take the *hair* of a Hindoo.
The *nose* of a Greek.
The *mouth* of the English.
The *complexion* of a German.
The *height* of a Norwegian.
The *feet* of a Chinese woman.
The *teeth* of an African.
The *arm* of a Belgian.
The *leg* of an Italian girl.
The *eye* of a Spaniard.
The *grace* of a Frenchwoman,
And you will have an American beauty.

We didn't know Max had met her. —*Max O'Rell.*

AMONG new drugs recently investigated are two of much promise, Cocillana and Naregamia Alata. The evidence thus far obtained from clinical experience would indicate that these remedies are likely to prove an important addition to the expectorants and respiratory stimulants now employed. In the spasmodic

cough of acute bronchitis, in the hacking cough of phthisis, and wherever there is marked interference with the respiratory function through accumulation of secretion of the inflamed membranes, these remedies are likely to prove efficient. Parke, Davis & Co., who have introduced these remedies, offer samples of them to physicians desiring to test them clinically, also reprints of articles concerning them, free of charge.

THE Health Board's mortality returns for the past week in New York city are as follows:

	Week Ending July 26.	*Week Ending July 19.*	*Average for Past Five Years.*
Small-pox	0	0	.7

THE PHILADELPHIA ACADEMY OF NATURAL SCIENCES.—Philadelphia is fortunate in the possession of an institution which, in its peculiar field, has no equal in this country and few superiors abroad; and unfortunate in its lack of appreciation or even knowledge of its special advantages. As the Academy of Natural Sciences, the institution in question, has just begun the erection of a more ample home for its scientific treasures, some account of its progress and present condition may be here in place.

This institution began its existence in a very humble way, and has, unlike its rivals, never received a cent of public aid, owing all it possesses to the liberality of the citizens of Philadelphia. It may safely be said that there is no other museum in existence comparable with that of the Academy in abundance and value of scientific material that has not been liberally aided by government money or by an ample original endowment.

Lest what is above said should be looked upon as an exaggeration, a brief statement of the extent and character of the collections in question may be given. In its representation of the feathered kingdom, for example, the museum of the Academy until recently surpassed all others; now there are three European collections with a greater number of birds. That of the Academy numbers about thirty-one thousand specimens, nearly all mounted.

In shells its collection is unrivaled, since it surpasses in this branch of natural history even the famous collection of the British Museum. The shells occupy about sixty thousand trays, and number in all more than half a million specimens. The conchologists of the Academy, who are among its most ardent students, have recently organized a society of American conchologists, which has been joined by most of the prominent students of this branch of science throughout the country.

In botany the Academy collection is of great extent and value. In flowering plants there are examples of more than thirty-five thousand species, and it is, of American herbaria, only surpassed by that made at Harvard College by the late Dr. Asa Gray, America's most distinguished botanist.

The cabinet of minerals is one of the most important in the country. It may be said that no other city in America possesses so extended, complete and valuable a series of mineral specimens, though Philadelphia is fortunate in possessing two such collections, one the property of a private collector.

In fossils, the Academy collection is one of the most important in America, and, so far as invertebrate fossils are concerned, probably the most extensive. It occupies some twenty thousand trays, and embraces some of the most valuable type specimens of our leading palæontologists.

The archæological collection, now crowded almost out of sight through lack of room for its proper display, is of high scientific value, and has but two superiors in this country. The entomological collection contains the largest series of North American insects in any museum. In other branches of science the Academy museum is little less rich and important; and it may safely be repeated that its collection of natural history specimens is among the most valuable and complete in existence.

Its library is no less valuable, being acknowledged to be the largest and most important collection of exclusively scientific works in America. In some directions, as that of conchology, it is measurably complete, no work of any value in the science being wanting. It numbers in all about thirty-five thousand valumes, including a large number of sumptuously illustrated folios, of almost incomparable value. —From an article by Charles Morris in August *Lippincott's*.

THE *Lancet* has made an extraordinary discovery which is likely to excite great interest in scientific circles. Even the comic papers appreciate the importance of the fact brought to light by the investigations of the *Lancet*. The discovery is thus alluded to in the current number of *Punch*:

According to *Mr. Punch's* sharp contemporary, the *Lancet*, the effect of bagpipe playing upon the teeth is to blunt them; in fact, in course of time, to wear them away. To the auditor the music has a contrary effect. *Mr. Punch* is able to say, from experience, that he has never listened to the National instrument of Grand Old Scotland without having his teeth set on edge.

The evil results of playing upon wind instruments upon the anatomical structures of the mouth appear strangely enough to have been overlooked. Now that the *Lancet* has directed attention to the subject, no doubt some ambitious member of the profession will give it his attention and prepare a paper for the Royal Society.—*Hospital Gazette.*

PATENT NEWS:—

TRADE-MARKS, ISSUED 22D JULY, 1890.

Artificial milk (The word "Kefyr")	A. Schnell	St. Louis, Mo.
Tonics and malt extracts (A star in outline with a circle upon the centre of the star)	Broening Bros	Lincoln, Neb.
Syrup of amorphine quinine (The word "Febriline")	Paris Medicine Co.	Paris, France.
Medicinal tablets (The word "Pan-Peptic")	Sharp & Dohme	Baltimore, Md.
Liquid ergot of rye (The word "Ergotole")	Sharp & Dohme	Baltimore, Md.
Liniment (The words "Pain Slayer")	C. Schlayer	Philadelphia, Pa.
Vegetable compound for certain diseases (The word "Kalmar")	A. Swanson	Jamestown, N. Y.
Bitters (The word "Beacon")	R. Y. McWilliams	New Orleans, La.
Carbonated beverages (The words "The Golden Key Brand" and representation of a key)	Union Bottling Co.	New York, N. Y.
Flavoring syrup for soda water	H. B. Mykrantz	Kansas City, Mo.
Compounded medicines (Heraldic garter; words: "The Home Medication Co.;" representation of a mortar and pestle, a flying dove, and the words: "Health, Purity, Beauty.")	The Home Medication Co.	New York, N. Y.
Perfumery (The word "Hasuno-hana")	J. L. Grossmith	London, England.
Pills (The words "Faber's Golden Female")	The Aphro Medicine Co.	Portland, Ore.
Remedy for dyspepsia, catarrh of the stomach, ulcers, and other microbian diseases (The word "Hydrozone")	The Drevet Manufacturing Co.	New York, N. Y.
Medicinal mixture for gonorrhœa, gleet, and all urinary troubles (The word and figures "Champion 12345")	L. Spingarn	New York, N. Y.

PATENTS, GRANTED THE 22D JULY, 1890.

Making acetic acid	I. A. F. Bang & M. C. A. Ruffin	Paris, France.
Producing bisulphites	C. Cornwell	Ypsilanti, Mich.
Bisulphite solutions	T. P. Burgess	Dedham, Mass.
Dental mold	L. F. Seeger, Jr.	Ahnapee, Wis.
Fracture apparatus	T. M. Miller	Medford, Wis.
Inhaler	J. D. Averell	Manchester, N. J.
Inhaler and respirator	H. F. Williams	Brooklyn, N. Y.
Obtaining oxygen from air	A. Brin	London, England.
Poultice-holder	C. S. Hirst	Philadelphia, Pa.
Surgical apparatus	W. L. Hendrick	Boston, Mass.
Surgical knife	G. Dittert	Neustadt, Saxony.
Surgical splint	L. Reenstierna	Boston, Mass.
Clinical thermometer case	H. G. Green	Brooklyn, N. Y.
Artificial tooth	C. H. Land	Detroit, Mich.

PATENTS, EXPIRING 22D JULY, 1890.

Abdominal supporter	J. W. Gurley	Petersburg, Va.
Breast-cup	A. M. Knapp	Lowell, Mass.
Inhaler	S. J. Shaw	Marlborough, Mass.
Milk of magnesia	Phillips & Reid,	New York, N. Y.
Medical compound	C. D. Bradley	Taunton, Mass.
Pessary	O. A. Muncaster	Washington, D. C.
Soda-water cooler	W. Gee	New York, N. Y.
Soda-water dispensing apparatus	J. Matthews	New York, N. Y.

LABELS.

Adhesive plaster (Title: "Casey's")	F. M. Casey	Mount Vernon, N. Y.
Title: "Davis' St. Vitus Dance Specific."	G. H. Davis	Philadelphia, Pa.

—CHARLES J. GOOCH, *Patent Attorney.*

SANTA FÉ RAILWAY EMPLOYÉS' ASSOCIATION.—From the annual report of the Association for 1889 the following items may prove of interest:

The total number of patients under treatment during the year was 17,390, as follows: 14,271 medical, and 3,119 surgical cases. As may be expected, the laborers constitute the largest number, 4,059; the smallest number under treatment were painters, 107; trainmen of all sorts constituting 4,584; 30 nationalities are represented.

Under the head of general diseases, 5,703 cases were treated, including malaria, 3,172; intermittent fever, 867; la grippe, 35; rheumatism, 649; and 277 cases of vaccination.

Respiratory diseases took 2,814 cases, of which 1,284 were bronchitis; 9, diphtheria; 135, pneumonia; 105, pleurisy; 28, phthisis, and 290, tonsillitis.

Digestive system diseases include 3,709 cases, 590 diarrhœa; dysentery, 484; dyspepsia, 620, and 1 case of intussusception of the bowels.

Skin diseases claim 309 cases, of which 141 were due to eczema.

Under nervous diseases were 992 cases, of which locomotor ataxia takes 3; neuralgia, 341; writer's cramp, 1.

There were 22 cases of heart lesions, 229 of the genito-urinary system, 410 of the eye, and 83 of the ear.

Under the surgical cases, there were 2,745 cases of simple fracture of all kinds, including 6 Colles fractures, 2 of the pelvis, 13 of the skull, and 1 of the spine. The were 34 cases of compound fractures of all kinds, including one crushed thorax, 419 sprains, 1,270 contusions, 37 dislocations, 162 cuts, 162 burns and scalds, 4 varicose ulcers, 23 hernia, synovitis, 17, killed, 29.

Besides the officers and those in charge of the hospitals, 127 local surgeons are employed to look after the sick and injured at various points.

Emergency boxes have been placed in all the way cars of freight trains on the system east of the Missouri River, and it is proposed to extend them to the entire system.

In the hospitals, 601 cases were treated, with 18 deaths; there was an average of 45 patients daily; 84,932 meals were given, 64,784 pieces washed, 6,661 prescriptions filled, and 140 operations performed.

TO CONTRIBUTORS AND CORRESPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the U. S. Navy for the two weeks ending July 26, 1890.

WHITFIELD, JAMES M., Assistant-Surgeon. Ordered to U. S. S. "Ajax," and other monitors.

WOOLVERTON, THEORON, Medical Inspector. Ordered to the U. S. S. "Philadelphia."

LOVERING, P. A., Passed Assistant-Surgeon. Detached from the U. S. Receiving-Ship "Wabash," and to the U. S. S. "Philadelphia."

BAILEY, T. B., Assistant-Surgeon. Detached from the U.S. Receiving-Ship "St. Louis," and to the U.S.S. "Philadelphia."

WHITE, S. S., Passed Assistant-Surgeon. Ordered to the Marine Rendezvous, San Francisco, Cal.

THE IMPORTANCE OF SURGICAL MEANS APPLIED TO THE NASO-PHARYNX IN THE RELIEF OF NASO-PHARYNGEAL AND MIDDLE EAR CATARRH.[1]

BY C. W. RICHARDSON, M.D.,
WASHINGTON, D. C.

AS a preface to the few remarks I am about to make, I wish to offer a few words in explanation; not in apology. During the early part of the present year, at the invitation of your secretary, I furnished him with the title of the present paper. Shortly after having written to Dr. Potter, I received a copy of the *Journal of the Respiratory Organs*, containing that most excellent paper read by Dr. Daly, before the New York Medical Society, carrying out, to some extent, the very idea and train of thought I intended following in presenting this subject for your consideration. I immediately wrote Dr. Potter requesting his permission to change my subject, to which he kindly consented, but, at the same time, urging me to continue its agitation. Concluding that the doctor's advice was well worthy of consideration, I decided to adhere to my original intention, and in a feeble way, lend my aid to the grand piece of "missionary work" already begun by the able exponent of rhinological wisdom, Dr. W. H. Daly.

In the presentation of this subject to-day, it is not my intention to array the rhinologist against the otologist, but simply to insist upon the necessity of the thorough surgical treatment of certain conditions existing within the naso-pharyngeal cavities as an aid to the radical removal of, and in preventing, the recurrence of certain affections of the middle ear. During the past decade, the intimate relationship existing between, or rather dependence of, diseases of the middle ear upon those of the naso-pharynx, has been so thoroughly recognized as to cause a great increase to that class of specialists, whose education from its incipiency has been such as to thoroughly imbue them with these ideas; whose education in the ear has been as thorough as in that of the nose and pharynx; whose education has been such as to cause them to view the diseases of the ear, in many cases, to be dependent upon an existing disease of these cavities; whose education has caused them to search for these causes, to remove them when present, and thus thoroughly to relieve their patients—to this class of practitioners, and as an humble exponent of these ideas, I claim to belong. Dr. Daly, in his presentation of the subject, has handled the otologist from a rhinological point of view; and the otologists have accused him, and indirectly the rhinal surgeons, with an incomplete knowledge of diseases of the ear. These exponents having clashed arms, it now remains for the auro-rhinologist to attempt to bring these warring factions to terms; bring harmony out of discord, and aid in showing the absolute necessity of the otologist being more of a rhinologist than ophthalmologist. I suggest that we aid in this good work because we are unbiased; we cannot be accused of wanting in knowledge of the use of the tuning fork; because, while being conservative, we do not hesitate in resorting to operative interference, when demanded, and, on account of having many ear cases presented primarily, we are better able to judge the relationship existing between diseases of the ear and those of the naso-pharynx. During my short experience as an auro rhinologist, it has been my lot to have had under observation a number of aural cases that have previously sought relief at the hands of skilled auro-

[1] Read at the Nashville meeting of the American Medical Association.

ophthalmologists in this vicinity and neighboring cities. These cases may be divided into two great classes, viz.: Acute and chronic inflammations of the middle ear cavity. Among the acute cases were many of recurring middle ear catarrh, non-suppurative and suppurative middle ear inflammations. In all the above mentioned acute affections there existed various affections of the nasal and pharyngeal cavities, in many of which their existence was so patent as hardly to escape the eye of the most non-observing layman. In some cases the aurist, who has been usually an ophthalmologist, while recognizing some disturbance of the normal functions of the naso-pharyngeal cavity, failing to appreciate its nature, has applied for its relief unscientific, inadequate, or inappropriate treatment, showing an utter disregard, want of knowledge, and frequent dread of the only proper therapeutic measures for the relief of the condition present, naso-pharyngeal surgery. The surgical treatment of these cavities would not have in view only the restoration of them to a normal condition, but also, by the light of our present knowledge, aid in a restoration of the impaired organ of audition, and, acting as a prophylactic agent, by removing the cause, prevent the recurrence of subsequent attacks. In many of the acute affections of the ear, in which there had been numerous recurrences, in the hands of otologists, I have almost universally found some affection of the naso-pharyngeal cavity the relief of which, by operative measures, not only aided in effecting a rapid recovery, but also produced an absolute immunity from subsequent attacks. These facts are so thoroughly acknowledged by all auro-rhinologists as to have become aphorisms, to cause me almost to apologize for having given them mention; but having done so I shall cite several cases to illustrate this point.

About two years ago I had placed under my care, by an otologist of Washington, a young woman who had frequent recurring attacks of middle ear catarrh. One attack would hardly be relieved before another would supervene. For years she had been under medical care for this annoying deafness, but invariably found that with exertion of all due care she was certain to find her efforts futile. My friend sent her to me that I might treat her throat, at the same time advising me to continue attention to the ears. He was the first medical attendant who had ever suggested the care to nose and pharynx. The pharynx was, with its thick padding of mucus, the most disgusting sight I have ever seen, the tonsils were enormously hypertrophied; the vault studded with stalactite-like hypertrophies; and the anterior and post-nasal orifices blocked by hypertrophies of inferior turbinates. The whole picture was changed within a few days by inter-nasal and pharyngeal surgery. While the patient was recovering from effects of active surgical procedures, several inflations were made, and she was discharged, within a short period, with no catarrh of nose, pharynx or ear, and so remains at present writing. Some time ago a patient was presented to me for examination. She had been under the care of various auro-ophthalmologists for several years for a chronic suppuration of the right middle ear, but not having obtained relief her parents had desisted in treatment. I found considerable glandular hypertrophy at vault of pharynx, and suggested the removal of the same as a possible means of aiding in the relief of the suppuration of the ear; as the child was about to leave town they did not consent to immediate treatment. Within six months an acute suppurative inflammation having occurred in the left ear, the patient was placed under my care. Removal of glandular hypertrophies at vault, with mild but effective treatment to ears, was followed within a few days with cessation of suppuration in the old, and within a couple of weeks in the recently affected one. I have seen this patient lately; hearing normal and no suppuration. Several cases of chronic middle ear catarrh have been under observation, that have received the most decided negative prognosis from distinguished auro-ophthalmologists; in these I have found naso-pharyngeal disease of an obstructive character, the removal of which, with simultaneous and subsequent use of inflation, has been attended with the most satisfactory results. Acute inflammation of the middle ear I seldom see without finding some obstructive disease of the nasal cavity or glandular hypertrophy at the vault of the pharynx.

The simple treatment of the ear affection without any attempt to remove the producing cause, as is the course adopted by the majority of aurists, leaves the case half treated; it leaves the patient, to say the least, open to a recurrence at any moment. It would be unnecessary to give a long citation of individual cases drifting into our hands, who would show the insufficiency of simple otological treatment. In speaking as I do, I do so only with regard to the locality in which I live and its environs. In Washington and Baltimore, the auro-ophthalmologist does not seem to recognize the great importance of naso-pharyngeal diseases, as productive of affections of the ears. If they do, their actions belie their opinions, and one must acknowledge that they are rhinal therapeutic-nihilists. Obstructive disease in the naso-pharynx, hypertrophies, polypismus, deflected septi and hypertrophial glandular tissue at vault of pharynx, are the conditions usually observed by me as demanding treatment in most of the cases coming under my observation. The *modus operandi* in the production of disease of the middle ear, through obstructive disease of the naso-pharynx, whether by interfering with the ventilation of the middle ear, by extension of catarrhal inflammation, by inflammatory filtration into or paralysis of tubal muscles, are questions of minor importance as compared to the great truth, now universally acknowledged, that these conditions are productive of the affections mentioned; and that the only consistent, scientific, rational, and, therefore, proper treatment, consists in the primary removal of the causative agent as essential to the secondary treatment of disease thereby produced. Even should the above assertion be challenged in general, or as regards any individual case, one cannot but admit that many of these cases, in the hands of the aurist and auro-ophthalmologist are allowed to continue suffering more or less inconvenience from unpleasant naso-pharyngeal affections, which the auro-rhinologist would at once recognize, and, simultaneously with the aural affection, relieve.

I cannot agree with the statement I have several times noted, made by a distinguished New York specialist, that atrophic rather than hypertrophic nasal catarrh is productive of the major proportion of middle-ear affections. Atrophic nasal catarrh, in which the nasal passages are extremely patulous, has presented the smallest per cent. of middle ear affections in my practice. In showing how inadequate the ordinary treatment of ear affections under the care of the auro ophthalmologist is, I do not wish it to be understood that I am to any extent an aural nihilist. I am afraid a great many of my medical confrères are claiming too much for the independent use of the forceps, cautery, snare, drills and saw. I doubt very

much of their curing all the ills to which the ear is subject, unless they at the same time resort to a judicious use of aural therapeutic measures. Firmly convinced, as I am, of the value of naso-pharyngeal surgical methods, I have not yet thrown away the leech, douche, paracentesis knife, Politzer's bag or catheter; our only safeguard is the judicious use of these means and the acknowledgment of their just therapeutic value. On the other hand, we must acknowledge the increased successfulness, or aid to success, in otological work rendered by the rhinal surgeon; but while acknowledging these achievements, one must remember that there are a vast number of aural cases falling under our observation thoroughly independent of any change within the naso-pharyngeal cavity; the affection in the one being synchronous with, but independent of, the affection in the other; the relief of the one not arresting the retrogressive progress of the other. It is almost unnecessary for me to state that I refer to sclerotic changes within the tympanic cavity. These cases are usually present in persons manifesting little or no change in naso-pharyngeal cavity, with patulous tubes. What aid can the rhinologist here furnish? If the patient is to have relief it must be through aural therapeutic measures employed in the hand of the skilled otologist. It is nonsense for one to agitate ideas having in view the condemnation of otological therapeutic methods—they have a vast field of usefulness. The otological surgeon existed and filled a field of usefulness before the rhinal surgeon was born. It is not a question of the younger but more thriving member devouring, as it were, the one which it claims to have so sorely afflicted, but rather a question of the more thorough amalgamation of the two branches; a more thorough appreciation of the dependence of aural affections upon naso-pharyngeal disease; a more thorough application of rhinal therapeutic methods in the treatment of aural affections by the aural surgeon—the aurist becoming more of a rhinologist and the rhinologist more of an aurist; a more thorough inculcation of these views in the aural and rhinal clinics of this country and elsewhere. Contrary to expressed views, one does not find either in aural clinics that careful examination and treatment of the naso-pharyngeal cavity as is carried out in rhinal clinics, nor in rhinal clinics that same care and attention to the ears that one finds in aural clinics; and appreciation of the inadequacy of the routine treatment of the case as resorted to by the auro-ophthalmologist.

Independent of the direct relationship and import of naso-pharyngeal surgery, as applied for the relief of affections of the middle ear, it also has an important direct action when applied for the relief of naso-pharyngeal catarrh. Coming before a body of experts in naso-pharyngeal diseases, it would seem almost unnecessary for me to refer to the important rôle that glandular hypertrophy and bursitis play in the production and continuance of naso-pharyngeal discharges. It would seem unnecessary, I say, to call attention to these important facts were they universally acknowledged and duly regarded. Most authorities agree and acknowledge that glandular hypertrophy at the vault of pharynx, when existing in sufficient quantity to cause more or less interference with nasal respiration, should be removed; but there is a want of unanimity when this tissue exists only in small quantity. There may be no doubt in the minds of many as regards the advisability of the thorough removal of all glandular tissue at the vault, possibly thinking that its existence there implies that it must perform some physiological function. In the normal condition, as shown by numerous examinations upon the living and dead, there exists no such excess of glandular tissue. I have been able, in a number of cases, to demonstrate the important rôle slight glandular hypertrophy and projecting knobs of adenoid tissue play in the production and in the continuation of naso-pharyngeal catarrh.

There exists, also, another condition at the vault in which there is what might be called a hypertrophical condition of the mucous membrane. The mucus surface, as noted at the choanæ, appears to be thrown into folds, and projects slightly beyond what appears to be normal. It is deeply injected, being well demarkated from the contiguous mucous surface; in other words, having very much the appearance of granulation tissue, as seen in the aural portion of the pharynx. The lateral chains of lymphatic tissue occasionally add an element. Bursitis may or may not be acknowledged. There exists a condition at vault that bears all semblance to this condition, and the influence it has in the production of excessive post-nasal secretion cannot be overlooked or underestimated. While insisting upon the important bearing the conditions just mentioned have in the production of excessive post-nasal secretions, and their removal by surgical procedure in the cessation of the same, I do not wish it to be understood that I offer them as the sole factors, or for an instant overlook other important elements in the production of this affection. What I wish to emphasize is the frequent dependence of post-nasal secretion upon local pathological changes such as those just mentioned, the removal of which will be attended with beneficial results. I do not insist upon any special surgical procedure—the forceps may be used with advantage in one case, the contrary in another.

In closing, I must thank you for your kind attention, and apologize for the rambling nature of my remarks and want of strict adherence to the text as given.

MENTHOL IN DISEASES OF THE AIR PASSAGES.[1]

By SETH S. BISHOP, M.D.,
Surgeon to the Illinois Charitable Eye and Ear Infirmary, Chicago, Ill.

MENTHOL is a peppermint camphor, a powerful antiseptic and local anodyne. I have used it considerably in a variety of diseases, and believe its remedial properties entitle it to an important place in the work of general practitioners and specialists alike.

To speak systematically concerning the effects of menthol on the upper respiratory tract, we will begin with the nose. Acute coryza or influenza in the first stage can be stopped by inhalations or sprays. If the attack is a light one nothing is necessary beyond smelling the crystals contained in a wide-mouth vial or tube. I have cut short colds in the head at their onset by such inhalations of thirty minutes' duration. This, of course, was before the nasal irritation had passed to the stage of inflammation. The sense of fullness and constriction about the nose and frontal sinuses, and the flow of mucus, disappeared, the nostrils opened for the free passage of air, and complete relief followed. This remedy is well adapted for such inhalations on account of its being very volatile.

In the later stages, where an actual inflammation existed before treatment began, it was necessary to use sprays of menthol dissolved in liquid albolene in

[1] Read before the Illinois State Medical Society, May, 1890

order to protect the membrane and keep the medicine in contact with the diseased surface a long time.

The strongest solution I have used was 20 per cent., but that is too powerful for most individuals; 5 or 10 per cent. solutions are as strong as people generally will bear without discomfort. The sense of heat is considerable at first, and it contributes to the comfort of patients materially to instruct them to take several prolonged inhalations of air directly after using the sprays. This converts the burning sensation into one of agreeable coolness.

Even in chronic cases of nasal catarrh I have been able to open a closed nasal passage by one or two treatments with a 15 per cent. solution, and afford great relief to mouth-breathers. Whenever a patient comes with turbinate bodies so enlarged as to obstruct the passage of air and prevent the entrance of sprays through the nostril to the throat, I resort at once to this remedy, with the effect of shrinking the engorged tissue and restoring the natural air channel.

It is advantageous to prescribe these inhalations in one form or another for persons who take cold easily, so that they can employ them at home whenever a cold is coming on. A drachm or two of the crystals in a wide-mouth vial with a metallic screw cap, or a glass tube, is a convenient device. A pledget of cotton should be pressed into the vial to prevent the menthol from working out and coming in contact with the nose; otherwise it will occasion smarting sensations wherever it touches the nostrils. If a large glass tube is used, both ends should be plugged with cotton-wool. As menthol does not melt at a temperature below 98° F., it can be carried in the pocket for ready and frequent use; when not in use, however, it should be corked, to prevent evaporation.

In prescribing it for patients to use in atomizers, it is best to use it not stronger than a 5 or 10 per cent. solution in oil or fluid vaseline. Albolene is preferable to vaseline, for the latter alone often proves irritating to the Schneiderian membrane.

In chronic hypertrophic rhinitis, with foul-smelling discharge, menthol is sufficiently antiseptic and corrective to lessen the amount of discharge and banish the odor. The peppermint aroma is usually agreeable, and more especially so when it supplants the stench of decay.

In atrophic catarrh the stimulating properties of this inhalant, combined with the emollient and protective qualities of albolene, affords a means of speedy improvement.

Pruritus nasi yields to nothing more readily than to menthol but cocaine, and in this connection, if it will not be too flagrant a tax upon our sense of continuity to pass from the upper air passages to the seat of pruritus ani, it will enable me to remark parenthetically that menthol is vastly superior to cocaine in its effects here. I have seen the most exquisitely torturing, itching and burning of the anus relieved in a few minutes by a 20 per cent. solution of this simple drug, after other ordinary and extraordinary remedies had utterly failed.

In laryngitis, not dependent on a rheumatic condition, menthol proves valuable. Even in rheumatic laryngitis it is an efficient adjunct to salicylate of sodium, iodide of potassium, etc. In simple acute laryngitis, if used in the early stage, it will relieve as it does in coryza, but the spray is the most effectual. When the soreness of the larynx and trachea and the hoarseness appear, a few inhalations of the spray often nip the attack in the bud. It relieves the hoarseness and imparts a smooth, reed like timbre to the voice. In advanced cases several inhalations of the spray should be used in the course of a day, and a continuous effect is often advantageous. This can be had by keeping a saucer heated in the patient's room, and dropping a few of the crystals on it occasionally during the day and night. They melt readily at a low temperature, and fill the atmosphere with their penetrating fumes.

In whooping-cough I have had patients inhale it constantly from a cloth saturated with the solution placed beneath the chin. Besides this I have sprayed the nose and throat daily, taking care to project the spray into the throat just at the instant of inhalation. The paroxysms of cough were lessened in intensity and frequency, and the course of the disease appeared to be shortened.

Bronchitis does better under these inhalations than with other topical applications or with internal medication alone. The spray should be taken following a forced exhalation, and retained as long as possible in the bronchial tubes before emptying the lungs preparatory to the next inhalation. This brings the fine, smoke like vapor in contact with the diseased surface. It is best to have patients exhale it through the nose, and it can readily be seen pouring out of the nostrils after a forced retention for several seconds, showing that the respiratory tract is thoroughly medicated. The effect is distinctly felt deep in the chest.

In catarrhal conditions of the Eustachian tube and middle ear I have employed menthol on account of its effect in relieving turgescence and stenosis in the nasal passages. And by the grace of the Eustachian tube we may properly speak of the tympanic cavity as a part of the air passages. I use the menthol in Buttle's inflator in the same manner as the iodine crystals, substituting cotton for sponges. If a stronger impression is desired, I use the liquid albolene solution. Simply throwing the spray against the Eustachian orifices with the De Vilbiss atomizer results in a thorough impression on the tube and tympanum.

Suppurative inflammation of the middle ear yields readily to the menthol treatment. Long standing cases have healed rapidly after an initiatory use of the 20 per cent. solution I have just seen several cases of this kind in which the purulent discharge ceased after a few such treatments.

Furunculosis of the ear has been in my hands more amenable to this than to any other remedy. A pledget of cotton, moistened with a 20 per cent. solution, should be so placed as to keep it in contact with the center of the furuncle. A warm or burning sensation follows, but soon gives place to one of coolness. The pain is relieved, the bacteria destroyed, and the swelling and discharge dissipated.

I have not yet tried it in hay fever, but have taken steps to have it given a thorough trial during the coming summer by the members of the United States Hay Fever Association.

In corroboration of my account of the behavior of menthol in my practice, I will quote briefly from a few authors on the subject:

Mr. Lennox Brown says: "Menthol contracts the capillary blood-vessels of the nose and throat, arrests sneezing and nasal discharge, stops pain and fullness of the head, and kills the microbe of infection. When the nasal discharge is excessive, it is checked; when deficient and thickened, as in hypertrophic rhinitis, its healthy character is restored, and when it is arrested, inspissated, and malodorous, as in atrophic rhinitis, fluidity is promoted and the foul smell corrected."

William Hill, of London, claims to have found menthol to be an excellent substitute for cocaine in hay fever.

Jones is authority for the statement that inhalations of menthol have proved useful in asthma. He used a 20 per cent. solution in olive oil, and relieved a case that resisted all the common remedies.

Nyes says these inhalations facilitate and diminish the expectoration in chronic bronchitis, and relieves the cough.

Potter and Knight have reported cases of improvement in laryngeal phthisis; and Rosenberg and others claim a large percentage of cures from the local application of menthol.

It is not my purpose to speak of the effects of this drug when administered internally, or when applied to the cutaneous surfaces for neuralgia, etc.; but excluding these uses, which are yet in the experimental stage, we are justified in according this remedy an important place in therapeutics.

70 State Street.

ETIOLOGY AND TREATMENT OF PNEUMONIA.[1]

By L. P. DEAHOFE, M.D.,
Potsdam, Ohio.

THE etiology of pneumonia is a subject of much interest, one upon which there is yet much difference of opinion.

Writers usually speak of age as a predisposing cause, and give three distinct periods of greatest liability, viz.: Childhood; between twenty and forty; and after sixty.

Statistics show, notwithstanding the frequency of catarrhal pneumonia in childhood, that it is five times more frequent in the first two years of life than in the next succeeding eighteen. It is most frequent between twenty and forty, and after sixty it becomes the most fatal of all acute diseases; nine-tenths of the deaths from acute diseases after sixty are from pneumonia. At the extremes of life the sexes are about equally affected, but between twenty and forty the male sex is affected nearly three times as often as the female, owing, no doubt, to exposure; this being a point in favor of the non-specific or non-microbic nature of the disease; but this may be explained in a different light, that of exposure to the infecting agent.

Opinion is divided as to whether the robust or the weakly are the more predisposed.

Convalescing from acute diseases, alcoholic excesses, anti-hygienic surroundings, diphtheria, erysipelas, measles, and other acute infectious diseases, are usually classed by writers as predisposing causes. One attack is said to predispose to another.

Almost every one classes cold as the chief and most frequent cause; such as prolonged exposure to severe cold, sudden chilling of the surface, etc., yet statistics show that cold does not markedly affect the pneumonic rate. Were there any direct relationship between cold and pneumonia we would expect the highest rate in January and February, but statistics will not bear it out.

All things which depress the vitality seem to predispose to the disease.

The fact that it is almost unknown in the Polar regions, and is not infrequent in the Torrid, shows that we must look for some other cause than cold.

Rainy seasons or moist districts do not influence the pneumonic rate to any great extent. Both wet and cold increase the bronchitis rate and the catarrhal processes, but not the pneumonic. Cerebro-spinal meningitis, diphtheria, influenza, measles and other diseases occur most frequently during the winter months, but nobody claims them to be due to cold.

In studying the etiology of the disease we are impressed with the fact that the less resistance the individual is able to offer to some specific influence the more liable he is to become affected with the disease.

Is pneumonia, then, an acute specific infectious disease, or a local inflammation?

That it is not a simple local inflammation has been amply proven by the experiments with air at different temperatures, with noxious gases, with caustic injections and traumatism; all of which have resulted negatively, and even more than negatively, for they have always resulted in lobular, instead of lobar pneumonia.

Exposure in close rooms and bad air is much more liable to bring on the disease than exposure out doors. Increased population gives increased pneumonic rate, a strong point in favor of the infectious nature of the disease, as all acute infectious diseases increase with over-crowding.

The symptomatology is against its being a local inflammation, for the relations of the amount of lung tissue involved and the severity of the symptoms do, not correspond, for upon post mortem, where the case showed the severest symptoms, high fever, delirium, convulsions, and heart failure, there has not been as much lung tissue involved as in cases not showing so severe symptoms.

There is no correlation of the local inflammation to the fever which accompanies it for awhile. It is rare when we have an extension of the disease to have a second chill.

High fever, with severe constitutional symptoms, and small consolidations, and *vice versa*, are the rule, not the exception. There is marked resemblance to the acute infections in the initiatory chill, the orderly pyrexia, typical course, symptoms following in regular sequence, peculiar countenance, herpetic eruptions, nephritis, cerebral symptoms, manner of commencement in young and old, viz.: convulsions in the former and coma in the latter; these all point to a specific microbic agent.

Epidemics of pneumonia are frequent in certain districts, in garrisons, and on board ships. Numbers of instances are on record where two individuals of the same family were simultaneously attacked. I have observed this myself. During the winter of 1883–84 a small epidemic occurred in my locality, where nine typical cases of pneumonia existed within an area of one square mile, and all in the country. They were all under my own observation.

Dr. R. J. Foulis reported an epidemic of pneumonia in which one hundred and fifteen cases occurred within a radius of two miles; the epidemic continuing from November, 1886, to January, 1887.

Several epidemics have occurred in Germany.

The complications of pneumonia ally it to the infections. I refer to peri- and endocarditis, to its cerebral and local complications. Again, cerebro-spinal fever has its lesion in the membranes of the base of the brain and cord; typhoid fever in the lymph structures of the intestinal tract; diphtheria in the epithelia, and pneumonia in the vesicular structures of the lungs.

The accepted treatment of to-day indicates that it is a specific disease. Taking all this together unquestionably favors the possibility of a microbic origin.

The idea of its being infectious dates back to the latter part of the eighteenth century. Klebs, in the

[1] Read before the Ohio State Med. Society, June 5, 1889.

Archives for Pathology and Pharmacology, Vol. IV., 1875, claimed to have found the infectious agent, which, upon being inoculated, developed pneumonia. He called it nervous pulmonale. Others have made similar claims.

Friedlander discovered the pneumococcus; but to Fränkel is due the credit of discovering the microbe of pneumonia, it being a diplococcus which, when inoculated, produces typical pneumonia.

A point of especial interest is that he found that a temperature of 106° invariably destroyed the germ, an observation worthy of consideration in the treatment of the disease.

From what has been said of the etiology of pneumonia, the rational treatment would of course be directed to the destruction of the microbe; but, unfortunately, up to the present, nothing has been tried that will meet this indication.

It has been urged on this account that the theory of the infectious or microbic nature of the disease is wrong. But certainly no one doubts the microbic nature of tuberculosis and a number of other diseases; and yet no germicide has been discovered that will cure them. On the other hand, remedies have been found that will effectually control certain diseases now known to be microbic in their origin, but not so known when first discovered. Malaria, for an example. Neither is it known how quinine cures malaria —whether it destroys the microbes, or whether it acts on the ptomaines generated by them.

Scientific research, however, is adding link by link, and ere many years will give us the whole chain, and enable us to effectually stop the ravages of all acute infections.

The treatment, then, must be symptomatic.

The pneumonic lung no more needs treatment than the intestinal ulcers of typhoid fever.

The first thing, then, of importance in the treatment of pneumonia is to place the patient in the horizontal position. The sick room should be large, cheerful, and well ventilated, the temperature of which should be about 70°.

Nothing is more grateful to the pneumonic patient than plenty of good, fresh air.

Pneumonia produces a greater shock to the nervous system than any other disease; hence, the patient should be placed in the best condition for resisting this shock. This can probably best be done during the developing stage of the disease, and until the pneumonic infiltration is completed, by hypodermic injections of morphine. The great relief which it procures to the patient is sufficient to commend it, especially in those cases attended by much pain.

A third indication in the treatment is heart insufficiency; and here I wish to emphasize the fact that heart insufficiency is not entirely, if at all, due to the high temperature, but to a nervous element.

For a flagging heart, the best remedy is an alcoholic stimulant judiciously employed, the pulse being the indicator, and the quantity administered must be determined by the effect upon the pulse. Begin with small doses, and watch their effect; if the this be beneficial, it will be noticed in a few hours, when the quantity may be cautiously increased.

A fourth indication, according to most authors (until a recent date), is to lower the temperature; which may be done by employing cold in different ways or by the numerous antipyretics now in use. But, as hinted at in my remarks on etiology, reduction of temperature is not a point of great importance; for, if the diplococcus cannot live in a temperature of 106°, why should we strive to reduce high temperatures, when high temperatures are the least favorable to the development of the microbe? Is it not nature's method of getting rid of the cause of the disease?

Many of our best writers are now abandoning the antipyretic treatment of pneumonia.

Dr. Jacobi, in the *N. Y. Med. Journal* in 1887, had already expressed himself as against it.

Dr. Ripley's experience, as detailed before the New York Academy of Medicine in the same year, is not favorable to their use.

Dr. Fruightnight's experience coincides with Dr. Ripley's.

Dr. Castle thinks that, if quinine be given in antipyretic doses, it is at the expense of nutrition.

Formerly I gave all my pneumonic patients antipyretics when the temperature reached 104°; but for the past three years I have abandoned the treatment altogether, and that, too, without the loss of a case.

If expectoration is difficult on account of viscidity, alkalies are indicated; if on account of muscular weakness, alcoholic stimulants are indicated.

If pain in the chest be severe, warm poultices may be made to envelop the chest; but this is rarely necessary if an opiate be used as directed above.

Refrain from all remedies which tend to paralyze the heart, and also avoid over-stimulation, as over-stimulation tends to paralysis.

And last, but not least, the patient should have a fluid or semi-fluid, highly nutritious diet, such as milk, eggs, and concentrated meat-broths, in small quantities at short intervals.

TREATMENT OF INEBRIATES LEGALLY.

By T. D. CROTHERS, M.D.,
Superintendent of Walnut Lodge, Hartford, Conn.

I HAVE received copies of papers with warm praises for the foreman of a Philadelphia jury, who insisted that a defense of intoxication in a murder trial should not be considered; "and, if it was, the courts might as well close and crime have full sway." An editor of a medical journal has caught the infection of this remark, and made it the theme of much commendation.

In Chicago a judge felt called upon to charge a jury in the same spirit, and predicted dire evils should any form of drunkenness ever be recognized as any possible excuse for crime.

These protests are the echoes of dying theories that already cast shadows over the justice and practice of law. These protests assume a degree of knowledge of the nature and character of drunkenness and the possible results of a different opinion that are deplorable, to say the least. The special features of the Philadelphia case are unknown to us; the Chicago case (which is only a type of many others) was that of a notorious inebriate, or rather one who had been seen intoxicated for years, and had been arrested many times for disorderly conduct and petty assaults, who now committed murder in a brutal way, killing a stranger and making efforts to conceal it.

The exaction of the highest penalty of the law in such cases is unjust, simply because the criminal does not possess the capacity to act and reason soundly, as other men. He is crippled in both body and mind, and cannot be judged by the standards of others who are not poisoned by spirits. This is the conclusion of all scientific study. Some of the best legal minds in England have recognized this in the past year. Baron Pollack charged the jury that, in estimating the criminal responsibility of an inebriate murderer,

his heredity should be considered in connection with the fact of his drinking at the time of committing the crime, not as an excuse for the act, but as a fact upon which the disposition of the case could be determined.

Chief Baron Falles directed the jury that a nurse should not be held accountable when, by reason of long-continued watching, her mental powers have been so worn out that a smaller quantity of liquor than ever affected her before rendered her more liable to become beside herself.

Lord Young refused to send to a jury a mother (accused of starving her baby), whence he discharged her with the regret that he could not send her to a home for inebriates, on the ground that drinking too much whiskey was not a crime and delirium tremens was a disease.

Mr. Justice Day ruled that, no matter what the cause may be of the unconsciousness, it is a question of knowledge of the nature and quality of the acts, and capacity to control such acts that governs the responsibility.

Dr. Kerr, of London, in a recent lecture, writes "the only plea for the execution of a person found guilty of a capital offense while intoxicated, that is at all plausible, is that based on economical considerations: namely, that it is cheaper for the State to hang the inebriate at once than to keep him in confinement for any lengthened period of time.

The plea of irresponsibility by reason of intoxication should be accepted not as an excuse for crime, but as a fact showing the incapacity of the accused to control himself or enjoy the liberty of a man in sound mind.

Where capital crime is committed in this State, the penalty should be confinement for life. If, after a term of years, a degree of recovery follows, such cases should go out on ticket-of-leave or parole depending on good behavior.

This should be the penalty not in the low sense of vengeance, but as a measure of self-protection to both the criminal and the community.

Physicians should educate the public and the courts that intoxication is a form of brain paralysis, and the acts of persons who are under the influence of spirits are never those of sound reasoning and full consciousness of their nature and consequences.

If the courts should recognize the disease of inebriety and establish the fact that acts committed in this state are to be considered evidence of the idiocy of the person, and, when repeated, are to be taken as proof of his incompetency to enjoy the freedom of a citizen, and entail on him confinement in a workhouse for periods of years or life-time, such a course would do away with all the mock sentiment and the dogmatic ignorance of trying to determine the degree of soundness and mental responsibility of inebriates. The questions of the courts would be confined to the facts of his use of spirits and his apparent condition after such use. This would require no expertness of medical men to determine.

At present great injustice and confusion prevails, and inebriety and crime are actually increased by the ignorant legal methods to check it. Thus John Jones is arrested for being intoxicated, and fined and sent to prison for ten days, over and over again. His family is impoverished and pauperized, and degraded in the eyes of the community, and are at last recruited into the army of paupers and criminals, and Jones is an incurable and burden on the taxpayers. If Jones' disease had been recognized at first, and he sent to an asylum for a period of years, his family could have succeeded in establishing themselves, and thus been saved from pauperism, and Jones might have been cured and come out a good citizen. At least Jones could have been made self-supporting, and his family would not have been pauperized by his insane conduct.

Physicians have one of the most important problems to determine in this question of drink-maniacs. The common opinions of these cases are very erroneous, and are flatly contradicted by all study of cases and all practical experience. The time has come for medical men to teach the public concerning this class, and not to accept the dictum of theorists and opinions of those who have no clear conceptions of these cases and their needs.

The Polyclinic.

PHILADELPHIA HOSPITAL.[1]

EPITHELIOMA OF THE LIP.

THIS case is one of epithelioma of the lip, or the so called "smoker's cancer." To have a cancerous affection we must have an irritant and a predisposition to cancerous growth in that spot. The great similarity to tuberculosis puts us on the track that we must hunt for its etiology.

The question of etiology of cancer is now in just the same condition that tuberculosis was twelve years ago. When is the most favorable time to operate on epithelioma? From the moment you have convinced yourself that there are epitheliai cells that have a tendency to return if removed, it is an indication that you have not removed the cause. Remove it before metastasis or infiltration of the neighboring lymph glands are invaded.

If you have infection of the glands, they all present the same appearance as if they had been infected secondarily from true carcinoma. The sooner the true epithelioma is removed the less is the chance for a general infection. Happily, in this case I have not detected any infiltration of the glands. Cut away sufficient tissue to satisfy your own mind that all diseased tissue is removed. Simple compression will stop the hemorrhage, and when the sutures are applied it will be entirely controlled.—*Laplace.*

SPEAKING roughly, a quart of oysters contains, on the average, about the same quantity of active nutritive substance as a quart of milk, or a pound of very lean beef, or a pound and a half of fresh codfish, or two-thirds of a pound of bread. But, while the weight of actual nutriment in the different quantities of food named is very nearly the same, the quality is widely different. That of the very lean meat or codfish consists mostly of what are called, in chemical language, protein compounds or "flesh formers"—the substance which makes blood, muscle, tendon, bone, brain, and other nitrogenous tissues. That of the bread contains but little of these, and consists chiefly of starch, with a little fat, and other compounds which serve the body as fuel, and supply it with heat and muscular power. The nutritive substance of oysters contains considerable of both the flesh-forming and the more especially heat and force-giving ingredients. Oysters come nearer to milk than almost any other common food; their values for supplying the body with material to build up its parts, repair its wastes, and furnish it with heat and energy would be pretty nearly the same.—*Cent. Mag.*

THE SALE OF POISONS.

IT does seem a pity that, with one Congress, forty-four Legislatures, and any number of City Councils, Burgesses, Selectmen, and other lawmakers of high and low degree, all burning to signalize themselves and benefit their fellowmen so greatly that another term in office will be forced upon them; we repeat, it seems a pity that we cannot have the sale of poisons properly regulated. A physician must be in practice for three years before he registers as a pharmacist, without examination; because the druggists exerted their influence. But every druggist in the land deals out Piso's consumption cure, that is said recently to have killed two persons; and Mrs. Winslow's soothing syrup, that has slain its hundreds of thousands; and Ayer's cherry pectoral, that dangerous preparation of prussic acid, the deadliest drug in existence. Any child can buy the most powerful poisons known, without the slightest difficulty, if they are only put into the form of a "patent medicine."

In this singular neglect we curiously follow the custom of our English cousins, who, like ourselves, are somewhat slow in moving for sanitary reforms or regulations that interfere with the freedom of trade. In England the sale of officinal narcotics, like paregoric, for instance, is hedged about by legislative enactments; while chlorodyne, a compound of morphine, prussic acid and chloroform, is dispensed freely by all druggists. Moreover, the Government stamp, which represents a duty paid by proprietary goods, amounting to a million dollars per annum, is supposed by the lower classes to be a Government pledge of the efficacy of the medicine.

In Germany, the Society of Apothecaries publishes in its journal the analysis of every new secret remedy, with a comparison of its fixed price and the cost of the ingredients. The Government requires an affidavit of the composition, verified by official analysis, and forbids the sale of any preparation containing poisons, unless the proportion is indicated on the label. Some are prohibited absolutely.

In Italy, the pharmacist is secured in his monopoly of dispensing drugs by an absolute prohibition of the supplying by physicians. He is also prohibited from dispensing any articles not specially permitted by the Pharmacopœia, except upon the prescription of a doctor. All proprietary medicines are submitted to the General Medical Council, with a statement of their exact composition. If the Council deem them safe and useful their sale is sanctioned; if the evidence is unsatisfactory, or if they are unsafe for use by non-medical persons, or do not possess the good qualities claimed, their sale is not permitted. In April last, two hundred proprietary medicines were placed upon the black-list.

As the vast majority of our people believe in amateur medicating, and nine-tenths of the men, and all the women, think themselves fully competent to interfere with the course of any disease, from corns to small-pox, it is too much to ask that the prescribing of drugs be confined altogether to the only class that can possibly employ them intelligently. Still, it is not unreasonable to ask that deadly poisons should not be sold indiscriminately, and put into the hands of the public, without a word as to their dangerous character, or any other directions as to their use than a lying claim of virtues of the panacea order.

Perhaps, some day, when we become civilized, we may obtain such a law.

EXALGINE.

THERE have been some unfavorable reports upon this drug, and in consequence it has fallen behind; but little of it is being called for at the pharmacies. Several observers, however, have obtained results from its administration which indicate the wisdom of giving it a more extended trial.

In the *British Medical Journal*, Herschell questions Atkinson's condemnation. Herschell says that two of Atkinson's patients had been habitually using morphine, and the third butyl chloral. It is a well-known fact that patients of this class rarely admit that anything else will do them good besides their accustomed narcotic. Herschell has obtained good results from the drug in seventy per cent. of his cases. In three cases of locomotor ataxia, exalgine gave relief from the lightning pains in two, and from the gastric crises in the third. In trifacial neuralgia, sciatica and herpes zoster of a severe type, the same drug gave prompt relief.

Farrar contributes a still more significant instance of the analgesic power of this drug. In a case of cancer of the liver, complicated with excruciating attacks of neuralgia of the face and head, for which many remedies had been tried without benefit, two-grain doses of exalgine, repeated every two hours, gave immediate relief. Indeed, the second dose cured the neuralgia; and in three months following the patient had not suffered a twinge of the pain.

A drug which will accomplish this much is not one to be cast aside as useless after a few unfavorable reports.

DURING the fortnight ending July 12 there were three hundred and fifty-eight cases of scarlet fever reported in London.

Annotations.

TRANSFUSION of blood in typhoid fever has been suggested as a means of supplying nourishment in extreme cases of debility. The special indication for this method is the impossibility of conveying food through the diseased intestinal glands to reach the thoracic duct. In the *North Carolina Medical Journal*, Dr. Jenkins records a case in which transfusion was employed to compensate for the loss of blood through intestinal hemorrhages. Seven of these had occurred, involving a loss of about two gallons of blood. Extreme exhaustion was the result; the patient was sinking rapidly, the pulse almost imperceptible, and respiration labored. Direct transfusion was performed, the blood being supplied by the common carotid artery of a lamb, and introduced into the patient's brachial vein. The enormous quantity of a quart of blood is said to have been introduced, though it is not stated how the measurement was taken. Immediate improvement was noticed, and rapid convalescence ensued.

MUSSEL POISONING.

MUSSELS are rarely used for food in this country, though in Ireland the poorer classes employ them. Cameron reports a case, in the *British Medical Journal*, in which a mother and four children died within two hours after eating stewed mussels. The chief symptoms were vomiting, dyspnœa, swelling of the face, incoördination of motion, and spasms —principally in the arms. The patients appeared to have died asphyxiated, their faces being intensely livid. The mussels had been procured from a small sheet of water which had access to the sea, but also received fresh water and sewage. They had brittle shells, and larger livers than mussels taken from the open sea. A leucomaine was extracted from them, corresponding to that described by Brieger as appearing in poisonous mussels. The author does not agree with Dutertre in his claim that the disease is never due to the food of the mussel. In nearly all the recorded cases of mussel poisoning they were in contact with sewage or stagnant water.

CHOLERA.

AS we predicted months ago, the cholera has spread to Mecca, and may be expected to go out from that city, with every returning caravan of pilgrims, to all parts of the Mahometan world. The French authorities are alive to the danger, and have endeavored to prevent the departure of pilgrims from their African dominions. This, however, is so difficult to do that it would have been wiser not to make an attempt which is sure to arouse the religious zeal of the natives in opposition, but rather to have regulated the pilgrimages in such a way that the return would be under the control of the authorities. The co-operation of the natives could thus have been secured, and the task of keeping out cholera perhaps rendered possible.

In Asiatic Turkey the epidemic has appeared near Diarbekir, and is advancing toward the Black Sea. Here it will probably prove a more potent defence against the Russians than will be afforded by the Turkish arms. If cholera becomes generally prevalent throughout the Turkish Empire, it will probably postpone the impending conflict for another year.

Letters to the Editor.

PYOCTANIN.

I FIND the enclosed paragraph in a daily paper, where, of course, it has no weight. If you have any particulars obtainable about this new remedy, do you not think it would be advisable to publish them in your interesting and ably edited paper?

SAN FRANCISCO, July 15, 1890.

NEW SURGICAL DISCOVERY.

Prof. Sittig, of Strasburg, has made the important discovery that pyoctanin, an aniline derivate, is an absolute destroyer of pus in any quantity. His new medicine is looked upon as the ideal destroyer of wounds, suppurations, ulcers, and skin affections, and is totally harmless. It is also highly diffusible, and has an immense sphere of utility. Taken internally, it is a remedy notable for pleurisy and peritonitis. Merck, of Darmstadt, has prepared all his surgical dressing material with this new discovery.

[We called attention to this substance in the issue of July 26, page 95, and the skepticism expressed there has been since confirmed. We have gotten over most of the delusions of youth, and no longer expect the earth, with a fence around it.—ED. T. & R.]

Book Reviews.

RECOLLECTIONS OF GENERAL GRANT. By GEORGE W. CHILDS. Philadelphia, Collin's Printing House, 1890.

If any man can be selected as the representative Philadelphian, it is George W. Childs. The qualities that have made the *Ledger* the great journal it is today, are those which distinguish Philadelphia, at her best. Unassuming worth, the industry that labors steadily and quietly, without noise and without hurry, and a correct judgment as to the needs of the day, are qualities we like to look upon as especially Philadelphian. Those unfamiliar with the currents of thought in the city, sometimes express surprise that the great success of the *Ledger* does not appear to excite antagonism from other journals. But Mr. Childs has not climbed to eminence by pulling down others. It is an oft-told tale, that of success by persevering, well-directed industry; and the road is open to every one who chooses to walk in it. The kindly nature of Mr. Childs has made his friendship prized by the greatest men of our time, and by none more than by General Grant. These "Recollections" give, what has always been eagerly received by the public, a glimpse into the private life of a great man. The world has very few such books, copious as is our literature in nearly every other department. Mr. Childs' reminiscences are as interesting as Boswell's, but presented with a dignity the sycophantic Scotchman could not assume.

Pamphlets.

VARICOCELE. By THOMAS W. KAY, M.D., Scranton, Pa. Reprint from *Cleveland Medical Gazette*.

The author describes two cases in which he opened the scrotum, with antiseptic precautions, cut down upon the veins and ligated them. By this method all danger of including the artery and thus causing atrophy of the testicle, is avoided.

EXTRA UTERINE PREGNANCY. The History of—By DR. G. W. MILTENBERGER. Laparotomy for; with Report of a Successful Case—By DR. T. A. ASHBY. Review and Discussion—By DR. H. A. KELLY. General Discussion. Papers read before the Obstetrical and Gynæcological Society, of Baltimore City, January 14 and February 11, 1890. Published by order of the Society.

The Medical Digest.

LINSLEY records a case in the *Medical Record* in which the urine presented a specific gravity of 1,050. The phosphates were in great excess. The symptoms were headache, anorexia, dullness and malaise; temperature elevated, and pulse rapid; but with no typhoid spots or marked symptoms of that disease. After more than four weeks, the symptoms continued.

OPPENHEIM contributes to the history of cerebral surgery a case of cerebral hemorrhage, with incomplete paralysis and clonic spasms. The symptoms were those of monoplegia facio-brachialis sinistra, headache and psychical anomalies. He opened the skull over the sulcus Rolandi, found a cystic glioma and removed its upper surface. Progressive improvement followed the operation.—*Med. Press.*

A PRACTICAL SUGAR TEST.—Nothnagel showed a handy test for sugar, which had been forwarded to him by Dr. Becker, of Cairo. It is simply a visiting card saturated with a solution of potash, over part of which is drawn a covering of the sulphate of copper, and the urine applied. The card is then laid on the globe of a lamp, when the saccharine urine will color the card brown, and this color will be the deeper the greater the amount of sugar.—*Med. Press.*

MYRTLE (*Med. Press*) records a case in which a double ovariotomy was performed in 1882, and the left kidney, with a portion of the mesentery, removed in 1889. After the latter operation an abscess formed, which, more than three months later, discharged through the left lung. The remaining kidney accomplished the work of two; the wound healed kindly; but deep seated inflammation set in early, causing suppuration diaphragmatic empyema, paralysis of muscle, fixing left thorax, adhesion of lung, and the abscess finally broke through to the bronchi. Recovery finally ensued.

CAUSES OF HÆMATURIA.—In 100 cases the causes were as follows:

Renal calculi	30
Enlarged prostate	20
Vesical calculi	14
Tumors, mostly malignant	13
Tubercle	6
Urethral stricture	5
Non-prostatic cystitis	3
Passage of calculi through ureter	3
Traumatism	2
Filaria sanguinis hominis	1
Doubtful	3

—Reginald Harrison, in *Med. Press.*

FRENNEL repeats the marvellous tales about ichthyol which followed its first appearance. The results of its intravaginal use are astounding. Cicatrices disappear in a few days, tubal pains abate, and erosions heal rapidly. Internally he gives 1½ to 3 grains thrice daily; and locally applies tampons of cotton with ichthyol, 5 parts to 100 of glycerine. When energetic resorption is demanded, he uses equal parts of ichthyol and lanoline, or 8 parts ichthyol to 80 of soft soap, rubbed over the abdomen. Erosions are painted with pure ammonium sulphichthyolate. In pruritus, a 10 per cent. lanoline ointment answers. If pain is great, 2 to 5 per cent. of chloral hydrate is added to the glycerine. After resorption has begun, he employs massage and electricity.—*Med. Press.*

TARNOWSKI has published a study of the physical peculiarities and the heredity of prostitutes and female thieves, as compared with a number of women of good character. All were of pure Russian blood. The author states that prostitution is followed by choice, and that the women return to it voluntarily when provided with other means of earning a living. The crania of these women averaged smaller than those of honest women; the prostitute's face was larger; her height was less; while signs of degeneracy, asymmetry of the face, malformations of the head, ears, teeth, palate, etc., were so frequent that 82 per cent. presented more than one such abnormality, against 2 per cent. among educated, honest women, and 14 per cent. of illiterate. Eighty-four per cent. of prostitutes and 16 of honest women had intemperate parents; and of the former class 6 per cent. had epileptic parents, 3 per cent. insane, and 4 per cent. were affected with hereditary syphilis. Without exception they were weak-minded or neuropathic.

The habitual thieves were physically and mentally superior to the prostitutes, though inferior to the honest class. Seventy-nine per cent. presented two or more signs of degeneration, 49 per cent. were of intemperate, 4 of epileptic, and 2 of insane parentage.

—*Amer. Jour. of Insanity.*

NERVOUS SYMPTOMS CONSECUTIVE TO DOUBLE CASTRATION.—It is curious that so little should be known in respect of the nervous and psychical troubles following removal of both testicles. Tradition tells us that eunuchs castrated before the advent of puberty assume certain feminine characteristics in respect both of mind and body. When the operation is performed after puberty, the corporeal changes are naturally less well marked, but the victims become irritable, melancholic, and devoid of energy and initiative. Although in Russia and elsewhere there exists sects, such as the Scopzys, who practice self-mutilation, their votaries do not afford much help in observing the effects of the deprivation, because nervous and psychical derangements may be supposed to precede the operation. Those who have to submit to the loss of the testicles for surgical reasons are by no means numerous, and they invariably withdraw from observation as soon as the wound is healed; and, moreover, the condition of their nervous system is usually masked by the predominating influence of the diathesis (often tuberculous), the local manifestations of which have necessitated the operation. In regard to females, our data are more numerous and exact. The climacteric period is well known to be associated with nervous and psychical troubles, and at this epoch the character and temperament become modified. Mental disease is frequent at this period, and the same morbid phenomena seem to result from the artificial menopause brought about by double castration. The most frequent symptoms are due to vaso-motor disturbances, which may go so far as to cause vertigo, and even simulate epilepsy. The psychical symptoms belong to the melancholic type, and not uncommonly terminate in dementia and suicide. Eleven out of thirty-three women operated upon were found by Claewecke to have developed these symptoms. According to Brown-Séquard they are attributable to the withdrawal from the blood of secretions, the reabsorption of which usually had an activating effect on the system generally.—*Med. Press.*

FATIGUE AND EXPERIMENTAL HYSTERIA.—The idea long since suggested itself, from close observation of the symptoms met with in hysterical women,

that the condition must be due to a lack of nervous energy—that is to say, a sort of paresis of the nerve centres which control the various organic and psychical functions. According to the *Revue Scientifique*, M. Féré has recently confirmed this supposition by demonstrating the close relationship which exists between phenomena resulting from a passing condition of fatigue, and those incidental to the more permanent condition of hysteria. For instance, in patients belonging to this category, the involuntary symmetry of muscular movements often shows itself in a very characteristic way. This symmetry, moreover, may be detected in healthy persons under the influence of fatigue, as well in epileptics after recovery from an attack. The physiological explanation of this fact is to be found in that the association of a voluntary movement on the part of another limb with that of a limb, the force of which is being measured, has for effect to increase the latter quantity. Another curious phenomenon, particularly well marked in the so-called "grands hysteriques," is the peculiar excitability which, under the influence of peripheral stimulation or suggested mental images, causes rapid and fugitive modifications of voluntary movements co-existent with similar modifications of sensation and nutrition. The same kind of excitability is developed in the case of fatigue. Fatigue, therefore, appears to constitute a veritable "experimental hysteria," standing, as it were, half-way between the normal person and the confirmed *hystérique*. Anything that tends to lower or depress the vital phenomena may therefore pave the way to an outburst of hysteria, the facility with which the latter is induced depending, of course, upon the normal vital energy of the patient. These facts explain the occurrence of traumatic hysteria, so frequent among males. In these cases, apart from any obvious transmitted or acquired predisposition, a violent shock or any other cause of sudden and excessive discharge of nervous energy may serve as the starting point of a neurosis which is practically indistinguishable from hysteria. These observations may assist in formulating a rational treatment for hysteria, prophylactic or otherwise.

—*Med. Press.*

Prolapse of the Ovary.—One of the most distressing and painful complaints to which the human female is liable is that of prolapse of the ovary. The commonest displacement as that which gives the most trouble as a rule, is generally backward and downward into Douglas's space, and is most frequently found in conjunction with retroflexion or retroversion of the uterus, and is more familiar to the gynæçologist than the other forms of displacemeet. The ovary enlarged from structural disease becomes congested and tumefied, more especially at or near a period, and a sudden fall or violent exertion, combined with a lax condition of the broad ligament, allows that organ to sink by degrees till the pain produced by the action of the bowel (more especially when allowed to become confined) is the first thing to direct the patient's attention to the complaint, and soon compels her to seek relief. Byford states, page 682, in his work On the Diseases and Accidents Incidental to Women: "The intimate and firm ligamentous connection of the ovaries with the fundus of the uterus causes them to partake of the changes in the position of that part of the organ. Thus when the fundus rises into the abdomen during pregnancy the ovaries are carrid up with it."

When the complaint has been of some duration, the ovary will easily be detected by the pain and feeling of sickness complained of by the patient when touched or pressed upon by the finger of the examiner, and which almost always makes the diagnosis unmistakable.

When the prolapsed organ is held down by adhesions, or a retroflexed uterus, it becomes a difficult matter to treat the case satisfactorily.

My own experience leads me to think that this affection is often overlooked, the flexion or version diagnosed only, and a pessary introduced, which, as Byford says (page 687), "Is pretty sure to cause pressure upon these sensitive organs, and soon become intolerable." My object in writing this paper is to call attention to the importance of examining more closely, in all cases of retroflexion (more especially of long standing), for a prolapsed ovary, before inserting a pessary which may do more harm than good, certainly add to the patient's distress, and bring discredit on a valuabie instrument. Examination per rectum in these cases is most important, the ovary can be more distinctly felt, as the examining finger can reach higher, and the organ can be palpated by a finger in both passages, if necessary. The treatment I adopt in these cases is the following:

I place the patient in the knee-elbow or knee-chest position, and the vagina being kept open by the duck bill speculum, the gravitation of the uterus forwards, assisted considerably by the atmospheric pressure on vaginal roof will (if the ovary be not bound down by adhesions) move upwards and out of reach of the examining finger.

If a Thomas' pessary (which is the one I prefer) be chosen of suitable size and fixed *in situ* so as to fill the roof of the posterior *cul-de-sac* the ovary cannot possibly regain its vicious position, and by keeping the bowels regular and restoring the general tone as much as possible by common-sense treatment, the patient will certainly be relieved, if not completely cured.

When we find the ovary bound down by firm adhesions, which will not give way under the influence of massage, and the patient's life becomes a burden, it is our duty to consider the removal of the offending organ, which, as a rule, is not a difficult operation, in this displacement easy access being had through posterior part of vaginal roof. The organ being drawn down by the ovum forceps, a ligature is passed round the pedicle and tied, and a scissors completes the removal. The incision should be left open for drainage; no necessity for sutures; vagina well syringed directly after the operation, and the rest left to nature.—Duke, *Med. Prees.*

The Transfer of Disease by Magnetism.—The department of therapeutical research taken up with such ardor and perseverance by Dr. Luys, of the Charité Hospital, at Paris, is not one which commends itself to the sober practitioner, and his more or less startling discoveries (?) invariably give rise to much hostile criticism on the part of those who see in this observer less a scientific investigator than one who is apparently unable to distinguish clearly between the real and the ideal. A year or two since he succeeded in exciting the attention of the French Academy of Medicine in reference to a very novel plan of treatment by drugs *à distance*, that is to say, he claimed to be able to produce the characteristic effects of varioas medicinal agents by merely exhibiting them to patients without actual ingestion. A committee of skeptics was appointed, and they reported conclusively that the effects were not such as had been claimed. Dr. Luy's latest sensation—communicated to the astonished world in the columns of

a lay contemporary—consists of the transference of diseases in hypnotized subjects by means of the magnet. So far as single individuals are concerned, the experiments have not exen the merit of novelty, for the transferenece of hysterical paralysis and similar subjective conditions from one side of the body to the other has over and over again been essayed, and not unfrequently with a certain measure of apparent success. Dr. Luys, however, goes a step further, and claims to have transferred the affection to a healthy subject, and in a manner and with a ceremonial which savors of the time when evil spirits were exorcised for the benefit of their host. It is quite impossible to take these experiments *au sérieux*, though in the hands of a clever writer they have proved capable of producing some very readable "copy." We have no prejudice against further observations in this disection, but it is only fair to the profession, as well as to a public ever avid of the marvelous, that they should be conducted on well-recognized principles, so as to eliminate the factor of auto-suggestion on the part of the observer.—*Med, Press.*

Here is the opportunity of their lives to the numerous wives who ardently desire that their husbands should have just one baby. Just apply to Luys and have the babe transferred—womb, ovaries, and all—to the guilty man.

FRENCH NOTES.

By A. E. Roussel, M.D.

Treatment of Insomnia in Children (Jules Simon).—We must at first seek the cause, which is often very difficult to discover. In most instances insomnia is due to dyspepsia. It is therefore necessary to question the parents on this subject; if the child is nursing at the breast, we must inquire as to the method by which it is being fed, examine the breast milk and ascertain whether the breast is not given at irregular intervals. We have often to deal with a child who is prematurely weaned, and who is given too rich food—alcohol and tea or coffee.

Insomnia is also often due to the fact that the evening repast is too copious; a child should always, even at the age of three or four years, eat moderately at night and only light food, such as eggs, chicken, etc.

The etiology once known, our first care should be to combat the cause by prescribing a severe hygiene. In some cases, when this does not suffice, or when we have been unable to discover the cause, we must act notwithstanding, and turn our attention to the hypnotics. What, then, are the hypnotics which may be prescribed for a child?

The first of these hypnotics is opium; it has been endeavored to remove this drug from infantile therapeutics, but, notwithstanding, it is the best of hypnotics. But we must not administer opium to a child who is constipated, who has anuria, or who is troubled with itching; these are the principal counterindications. Prescribe laudanum in doses of half a drop under one year of age, and one drop additional for each year, in a potion.

The syrup of codein is a good hypnotic, admirably supported by little children. At the age of one year, a teaspoonful of this syrup in a potion; under one year of age, half a teaspoonful.

The bromides are often useful; we give thirty centigrammes at six months of age, fifty at one year, administered at night, taking care to interrupt the indications after five or six days, to be renewed subsequently.

Chloral is an excellent hypnotic, without danger; it can be given in the same doses as the bromides, and the best way to administer it is by enema. We use a simple enema to clean out the intestine, then the chloral, associated with camphor or musk, with the yelk of an egg and a small quantity of water.

Chloral is especially useful when the child is threatened with convulsions, when there is present hiccough or twitchings; insomnia is in effect often the prelude of convulsions.

In some cases, antipyrine by enema in the same doses as the chloral or the bromides, is a good medicament.

There are also other hypnotics which should not be neglected, such as laurel water, musk, ether and valerian.—*Le Bulletin Medical.*

Medical News and Miscellany.

Scarlet fever is steadily increasing in London.

The rumors of an epidemic of typhoid in Bethlehem are unfounded.

At Brunn, Austria, permanganate baths are used for small-pox, with asserted benefit.

Surgeon General Gordon states that tropical Africa cannot be colonized by the English race.

The Chicago doctor's claim that water will cure consumption applies with particular force to the consumption of whisky.

To endure the rigors of winter may require fortitude, but to endure the rigors of this summer requires 92d.—*Washington Star.*

Pennsylvania doctors who have practiced three years are entitled to register as druggists without examination.

Thanks, awfully!

An Ohio girl sued a railroad company for injuries resulting in an ovarian tumor. An operation being decided necessary, the surgeon opened her abdomen and found a dead, full-term fœtus. The railroad pleaded "not guilty."

Representative Cornbread: "Doctor, I wish ye'd give me some medicine."

Doctor: "What's the matter?"

Representative Cornbread: "I dunno; but every time I open my mouth the Speaker tells me I'm out of order, an' I thought I might ez well hev it 'tended to."—*Washington Post.*

Sometimes the inherent cussedness of things seems to be suspended, and events occur with a certain degree of aptness. Just as the diplomas were about to be delivered to a First Aid to the Injured class in London, a boy was run over by a cart, in the neighborhood, and the members at once proceeded to demonstrate their proficiency.

Dr. Frank Bosworth, of New York, concludes, from a careful study of the subject, that no country in the world has more valuable mineral springs than are to be found in the United States, and that a thorough test of their properties by medical men, and the adoption of systematic regimen, with a view to regulating cures, would secure them popular recognition.

PROFESSOR S. G. DIXON has taken his family to the Maine coast.

THE cholera, on July 31, was causing eighty deaths daily in the city of Mecca.

PROFESSOR J. M. ANDERS has burned his ships by selling his Eighth street house.

NEW ORLEANS has quarantined against Port Limon, Costa Rica, for yellow fever.

A LOUISVILLE doctor, aged eighty-one, has just married his sixth wife, aged forty-one.

PROFERSOR J. E. GARRETSON has gone for the remainder of the summer to Castine, Maine.

DR. W. G. STEVENSON, of Poughkeepsie, a prominent member of the Board of Education, died recently.

THE Senate of France has voted twenty thousand dollars for the establishment of frontier guards against cholera.

OVER four hundred women and children were sent to the country last Thursday by the Children's Country Week Association.

AT the W. C. T. U. Camp, at Valley Forge, Dr. Caroline M. Dobson conducted a School of Methods in hygiene and heredity.

DURING July 5,197 boys, 1,196 men, 1,043 women, and 2,542 girls used the free baths of the Bedford Street Mission, at 619 Alaska street.

DR. WILLIAM BRODIE, aged sixty-seven years, one of the best known physicians in Michigan, died, on Wednesday evening, at his home in Detroit.

THE useless fastings of such men as Succi has caused the coining of the useless word "asitia," to denote the state produced by voluntary starvation.

A CHIROPODIST bears no relation to a clog-dancer merely because he is in the healin' toe business.
—*New York News.*

THE Children's Sea-shore House is full to overflowing, but its funds are nearly exhausted. Three thousand dollars are needed for the next five weeks.

AT a concert and tableaux entertainment given at the Hotel Bellevue, Wayne, $225 was realized for the benefit of the Children's Country Week Association.

DURING July the Milk Inspector examined 8,799 quarts of milk, of which 1,558 were condemned. The percentage of milk adulterated or partly skimmed was 17.7

DR. H. B. BRUSSTAR, Lazaretto physician, has replied to the resolution of the Health Board in reference to the admission of persons to the Lazaretto Station without permits.

THE Sanitary Council of Alexandria has issued orders that the regulations to prevent the introduction of cholera into Egypt be strictly applied to vessels from Red Sea ports.

OVER one hundred men employed in the Philadelphia and Reading machine shops at Reading are off duty, owing to illness, most of them suffering from dysentery in its worst form.

THE Philadelphia public baths were patronized last week by 111,317 persons. This number would doubtless have been much larger if the bathing facilities permitted, as crowds were turned away who could not be accommodated.

ONE hundred years ago July 31 the first mechanical patent was issued by this Government. It was granted to Samuel Hopkins for making pot and pearl ashes. The total number of patents issued during the century was 433,432.

IT is stated that a Bohemian has discovered a combination of chemicals, by the use of which the hardest stones can be dissolved and moulded into any shape, the "cast being as hard as flint, translucent, and capable of taking on a brilliant lustre."

DR. GEORGE F. ROEHRIG has called the attention of the police to the cases of two children who were seriously ill from the effects of eating samples of sugar-coated pills, which were distributed on the street. The children mistook the "patent medicine" for candy.

THE monthly report for July of St. Mary's Hospital Dispensary shows the total number of visits, 1,864; number of new cases, 531; accident cases, 224; eye cases, 478 old and 83 new cases. Eighty cases were admitted to the house; of these 22 were surgical and 58 medical.

INFORMATION has reached Bonne Bay, Newfoundland, that a violent outbreak of diphtheria has occurred at Red Bay, a fishing settlement on the Labrador coast. The place is in a bad sanitary condition, and more than half the people are ill. The only hope is that a British war ship will go to the rescue with doctors and medicines.

MANUEL GORUTUS, a young man who came to this country from Yucatan some time ago, has been sent to the pest house, on North Brothers Island, as an incurable leper. His disease is what is called anæsthetic leprosy, a variety of the terrible disease characterized chiefly by numbness of the parts affected.

BY means of two instruments, which he calls the "neomatchograph" and the "neomatchometer," Prof. Donder, of Utrecht, has discovered that it takes the brain one .067 of a second to elaborate a single idea. It is a great waste of time to devote one .067 of a second to some of the ideas elaborated—and this may be one of them.—*Norristown Herald.*

THE International Medical Congress is by this time a thing of the past. On the opening day it was said that five hundred American doctors were in attendance. Surgeon General Hamilton responded to the address of welcome. Meanwhile, the Berlinese are treated to a specimen of American tropical weather, August 4 being the hottest day within ten years, and twenty sunstrokes occurring.

THE Committee of the Countess of Dufferin's Association for providing female medical aid for the women of India, have offered a scholarship of $500 for competition amongst the students of the Edinburgh School of Medicine for Women. The successful candidate must qualify for medical practice in India in connection with the association. The conditions on which it is to be awarded are not yet settled.

IT is so seldom that milkmen are actually caught watering their milk that the finding of one in the act in Paris recently was deemed a worthy enough piece of news to be sent as a special to London. He was working the pump when the officers put in an appearance, and he said: "Ah, well, you have fairly caught me this time. Jump up on my cart and I will drive you to the police office, to save you trouble."

SECRETARY JOHNSON, of the Indiana State Board of Charities, reports that there is in one of the institutions of that State, a girl who has a face and some of the characteristics of a pig. She realizes her affliction, and avoids strangers in consequence. This is where she differs from many males, who resemble her in the possession of porky characteristics, which they always intrude on strangers.

DR. ERNEST VON BRUECKE, the noted physiologist, who opposes vivisection, has retired from the faculty of the Vienna University, after an uninterrupted course of forty-one years' teaching at that institution. He is pensioned off under an Austrian law that requires the retirement of professors and State functionaries who have attained the age of seventy years, though still in the prime of his mental powers.

THE place of Dr. B. W. McGilland, Resident Physician of the Presbyterian Hospital, whose term of office expired recently, will be filled by Dr. Howard S. Anders, the Junior Physician. The men's surgical and children's wards will be under the charge of Dr. W. C. Posey, and Dr. J. Robinson will hereafter be at the head of the women's surgical ward. Dr. Barker, a new resident, will look after the men's and women's medical wards, as well as the ambulance service.

THE Secretary of the Christian's Home for Intemperate men, of New York, complains "that there is an unwillingness, a prejudice based on misconception or on erroneous teachings, which inclines many to try any and every thing except moral force to correct an immoral thing." He says that although this Home has been in active work for twelve years, and nearly three thousand men have been treated, one-half of whom are "standing witnesses to the power of grace," or cured, in their meaning, the fact remains that we have never been able to fill the Home to its full working capacity. The Christian Home and the principles on which it is based belong to an earlier age of the world, the age of credulity. All scientific advance is fatal to its prosperity. Nothing but change and adapting itself to the clearer light of the age will prevent a certain death.—*Jour. Inebriety.*

YOUNG DOCTOR STUNNING: Do you know, dear, I never thought to ask you if the census enumerator interviewed you?

His Fiancé: Oh, yes, Charlie. He came and I told him that I had a specialist in chage of my case, who had discovered strong symptoms of a serious affection of the heart, and I thought he'd better put it down as both "acute" and "chronic."

—*Boston Saturday Evening Gazette.*

TOMATOES FOR DYSPEPSIA AND BILIOUSNESS.—Communication in the *Pall Mall Gazette.* "Mr. Editor:—Having been a sufferer from biliousness and dyspepsia for a great many years, and having tried all sorts of medicines without success, I was recommended to try the effect of tomatoes. The result has been marvelous. I can safely say that since the tomatoes have been in season, I have only had one attack—and that a slight one—of this disagreeable complaint. I think you would be doing the public a service in drawing their attention to this simple but effective remedy."

NEW PATENTS:—

PATENTS GRANTED JULY 29TH, 1890.

Abdominal supporter	H. E. Rogers	Portland, Me.
Inhaler and spirometer	W. A. Shepard	Elgin, Ill.
Dental vulcanizer	J. E. Quinn	Boston, Mass.
Inhaler	G. W. Nutz	Philadelphia, Pa.
Artificial leg	G. Beacock	Brockville, Ont.
Pharmaceutical powder-divider	W. F. Dessau	Chicago, Ill.
Surgical splint	G. Beacock	Brockville, Ont.
Salve	J. J. Ryan	Brooklyn, N. Y.
Electrical syringe	J. H. Woodward	Seward, Nebr.
Temperature regulation	R. J. Pratt	Greenbush, N. Y.

TRADE MARKS ISSUED JULY 29TH, 1890.

Medical remedies (A portrait of the face of Dr. John Swinburne, formerly of Albany, N. Y.)	W. G. Lewi	Albany, N. Y.
Medicated tooth-picks (The representation of a rustic diamond-shaped frame formed of tooth-picks inclosing the words "Medicated Tooth Picks")	E. E. Burson	Rockford, Ill.
Remedy for diseases of the digestive organs (The word "TRYPHOSA")	F. N. Class	New York, N. Y.
Medicines for certain diseases of men and animals (A portrait of the registrant)	E. S. Sloan	Boston, Mass.
Chemical preparation for bleaching purposes (The word "OZONINE")	The Drevet Manufacturing Company	New York, N. Y.
Remedy for the destruction of Bacteria, Microbes and Germs in the human system (The word "GLYCOZONE")	The Drevet Manufacturing Company	New York, N. Y.
Florida water (The representation of a vase containing a white, a red, and a yellow rose)	The American Florida Water Co	New York, N. Y
Remedy for wounds (A circular band, at opposite sides of which are arranged two crescent-shaped figures)	Sommer, Bros.	New York, N. Y.

LABELS ISSUED JULY 29TH, 1890.

Title: "Half Dollar Box of Chemicals"	Harry I. Corbitt	Brooklyn, N. Y.
Title: "Medicated Food"	John Elliott	Indianopolis, Ind.
Title: "Glycozone"	The Drevet Manufacturing Company	New York, N. Y.
Title: "Syrup of Figs"	California Fig Syrup Company	San Francisco, Cal.

PATENTS EXPIRING JULY 29TH, 1890.

Manufacture of chlorine	H. Deacon	Lancaster, England.
Disinfectant compound	J. Hilton	New York, N. Y.
Pessary	F. P. Banning	New York, N. Y.
Dispensing syrup in soda water	J. Matthews	New York, N. Y.

—Charles J. Gooch, *Patent Attorney.*

DR. JOHN A. WYETH, of New York, has consented to deliver the address before the Mississippi Valley Medical Association, at its annual meeting, in Louisville, October 8, 1890. Quite a number of prominent medical men in the Mississippi Valley have given in titles of papers to be read, and promised to attend and take part in discussions. A large and profitable meeting is already assured. Dr. Frank Woodbury, of Philadelphia, will read a paper. The profession of the Mississippi Valley are especially invited to be accompanied by their wives, for there may be expected great things socially as well as scientifically, and the ladies always have a good time in Kentucky. Titles of papers to be read are sent to the secretary, Dr. McKee, 57 West Seventh street, Cincinnati, who would also be glad to receive reprints or copies of all papers read at the last meeting, to make the collection as complete as possible.

THE SPANK CURE.—The Chicago *Inter-Ocean* remarks, quaintly but sensibly:

"Among the good old customs which are falling into disuse, that of spanking the coming generation into behaving itself is leading the procession. There are no such spankings now as there used to be in my time, and I am sorry for it. Things in the spank line are certainly degenerating, along with the drama, the flavor of strawberries, and phenomenal weather, as the years go by. Children just entering the heated, base-burning epoch of spankhood now have "nerves," and must be humored. They get to balking and skulking, and the family physician is called in when the good old housewife remedy of a warm application of slipper is all that is needed.

"The spank cure is not appreciated in this generation as it was in the last. Looking back on a stormy and tempestuous career in the wood-shed with Jones *pere* at the helm, I now feel like writing him a kind and encouraging testimonial on the efficacy of his unapproachable spank treatment, although at that time I felt more like kicking him in the shins, and, I regret to say, sometimes gave vent to my emotions."

TO CONTRIBUTORS AND CORRESPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 11, 1890, to July 16, 1890.

By direction of the Secretary of War, leave of absence for three months, to take effect September 15, 1890, or as soon thereafter as his services can be spared, is granted Captain William H. Arthur, Assistant-Surgeon. Par. 1, S. O. 160, A. G. O., Washington, D. C., July 11, 1890.

By direction of the Secretary of War, the leave of absence on surgeon's certificate of disability granted Captain Louis M. Maus, Assistant-Surgeon, in S. O. 4, January 6, 1890, from this office, is extended six months, on account of sickness. Par, 16, S. O. 160, A. G. O., Washington, D. C., July 11, 1890.

By direction of the Secretary of War, leave of absence for four months, on surgeon's certificate of disability, with permission to leave the Division of the Missouri, is granted Captain William H. Corbusier, Assistant-Surgeon. Par. 4, S. O 163, A. G. O., Washington, D. C., July 14, 1890.

Leave of absence for one month, to take effect the 30th instant, is granted Col. Charles Page, Assistant-Surgeon-General, Medical Director of the Department. Par. 3, S. O. 91, Department of the Missouri, St. Louis, Mo., July 14, 1890.

By direction of the Secretary of War, leave of absence for two months is granted Captain John F. Philips, Assistant-Surgeon. Par. 4, S. O. 164, Headquarters of the Army, A. G. O., Washington, July 16, 1890.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service for the three weeks ended July 26, 1890.

BAILHACHE, P. H., Surgeon. Granted leave of absence for seven days, July 26, 1890.

HUTTON, W. H. H., Surgeon. To proceed to Chicago, Ill., on special duty, July 24, 1890.

GODFREY, JOHN, Surgeon. Granted leave of absence for thirty days, July 21, 1890.

PECKHAM, C. T., Passed Assistant-Surgeon. When relieved at Memphis, Tenn., to proceed to St. Louis, Mo., and assume command of the service, July 9, 1890.

DEVAN, S. C., Passed Assistant-Surgeon. Granted leave of absence for twenty-five days, July 15, 1890.

KALLOCH, P. C., Passed Assistant-Surgeon. Orders of July 5, to St. Louis, Mo., revoked July 8, 1890.

WILLIAMS, L. L., Passed Assistant-Surgeon. Relieved from duty at Baltimore, Md., and to assume command of service at Memphis, Tenn., July 8, 1890.

PERRY, T. B., Assistant-Surgeon. To proceed to Baltimore, Md., for temporary duty, July 17, 1890.

STONER, J. B., Assistant-Surgeon. Granted leave of absence for thirty days, July 21, 1890.

HUSSEY, S. H., Assistant-Surgeon. To proceed to Pittsburgh, Pa., for temporary duty, July 18, 1890.

YOUNG, G. B., Assistant-Surgeon. Granted leave of absence for fifteen days, on account of sickness, July 12, 1890.

STIMPSON, W. G., Assistant-Surgeon. To proceed to Buffalo, N. Y., for temporary duty, July 12, 1890.

HOUGHTON, E. R., Assistant-Surgeon. To report to the Medical Officer in command, New York Marine Hospital, for temporary duty, July 14, 1890.

PROMOTION.

MAGRUDER, G. M., Passed Assistant-Surgeon. To rank as such from July 12, 1890.

APPOINTMENTS.

HOUGHTON, E. R., Assistant-Surgeon. To rank as such from July 12, 1890.

BENEDICT, A. L., Assistant-Surgeon. To rank as such from July 24, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending August 2, 1890.

BLACKWOOD, N. J., Assistant-Surgeon. Ordered to duty in the Bureau of Medicine and Surgery.

WALES, P. S., Medical Director. Ordered to duty in charge of the Museum of Hygiene.

STONE, L. H., Assistant-Surgeon. Ordered to the U. S. Receiving-ship "New Hampshire."

URIC, J. F., Assistant-Surgeon. Detached from the U. S. Receiving-ship "New Hampshire," and ordered to the U. S. Receiving-ship "Wabash."

NORTON, OLIVER D., Passed Assistant-Surgeon. Granted leave of absence for month of August.

BABIN, H. J., Surgeon. Granted one month's leave of absence, from July 23.

AUZALL, E. W., Assistant-Surgeon. Detached from U. S. S. "Galena," and wait orders.

ECKSTEIN, A. C., Surgeon. Granted leave of absence for month of August.

PENROSE, T. N., Medical Inspector. Granted leave of absence for two weeks.

CABELL, A. G., Passed Assistant-Surgeon. Granted leave of absence for the month of August.

ASHBRIDGE, RICHARD, Passed Assistant-Surgeon. Granted one month's sick-leave.

HEYL, T. C., Surgeon. Granted leave of absence for the month of August.

COOKE, GEO. H., Medical Inspector. Detached from Navy Yard, League Island, and to the "Pensacola."

WHITE, C. H., Medical Inspector. Detached from the "Pensacola," proceed home, and wait orders.

HOEHLING, A. A., Medical Inspector. Detached from Naval Hospital, Washington, and to League Island Navy Yard.

WELLS, H. M., Medical Inspector. Detached from Museum of Hygiene, and to Naval Hospital, Washington, D.C.

Medical Index.

A weekly list of the more important and practical articles appearing in the contemporary foreign and domestic medical journals.

Devoirs du médicin patricien et des administrations hospitalieres en presence d'une maladie infectieuse, Brunon. La Normaadie Méd.
Der gegenwärtige Stand der Lehre von den Hallucinationen, Mendel. Berl. Klin. Wochenschrift.
Despre actinnea therapeutica a acidului di-iodo-salicylic, Calalb. Clinica.
Despre iodhydratul de iodat de chinina in tratramentul accidentelor syphilitice secundare, Tzonicu. *Ibid.*
Despre aristol, Romano. *Ibid.*
Des tumeurs adenoides chez les adultes, Raulin. Revue de Laryng. D'Otologie.
Des mesures propres à rendre moins faible l'accroissement de la population de la France, Lagneau. Bull. de L'Ac. de Méd.
Du champ d'action du thermo-cautere, Panas. *Ibid.*
Departure from 98.4°; or a plea for a practical method in medicine, Frere. Prov. Med. Jour.
Dilation of the heart, some forms of, Handford. *Ibid.*
Di alcune condizioni patalogiche sperimentali che modificano l'attivita microbicida del sangue, Bonome. La Rif. Med.
Die Medianstellung des Stimmbandes bei Recurrenslähmung, Wagner. Arch. f. path. Anat. u. Physiol.
Die angebornen Kiemenfisteln des Menschen, ihre anatomische Bedeutung u. ihr Verhältniss zu verwandten branchiogenen Missbildungen, Kostanecki. *Ibid.*
Das perforirende Geschwür der Nasenscheidewand. Eine anatomisch-klinische Studie, Hajek. *Ibid.*
Der knöcherne Ersatz grober Schädeldefekte, König. Centralblatt f. Chirurgie.
Della distruzione dei microrganismi durante il processo di infiammazione. La Rif. Med.
Des chlorals, Sée. La Méd. Mod.
Du traitement hygienique de la tuberculose, et specialement de la cure à l'air et au repos, D'Aremberg. Bull. Général de Therapeutique.
Etiology and local treatment of phthisis pulmonalis, Shurly. Amer. Jour. Med. Sciences.
Early operative interference in acute peritonitis, Lydston. Jour. Amer. Med. Ass'n.
Exploratory Laparotomy, medico-legal aspect of, Wilde. *Ib.*
Electricity in ear-diseases, Jones. *Ibid.*
El microbia de la malaria o su evolucion en la sangre de los intoxicados. Confirmacion del descubrimiento de Mr. Laveran, Goronado. Cronica.
Estado de las defunciones y niemaientas del termino municipal de Marianao, ocurridas en el segundo semestre de 1889, Unance. *Ibid.*
Epilepsy and depressed skull-hæmorrhagic pachymeningitis and concussion, Osgood. Brooklyn Med. Jour.
Epulis, report of five cases, Rogers. Virginia Med. Monthly.
Etiology of diphtheria, Klein. Occid. Med. Times.
Extirpation of the thyroid gland, Huntington. *Ibid.*
Etiology of pleuritis, especially in its relation to tuberculosis, Smith. Med. News.
Extra-abdominal intestinal surgery, and the use of animal membranes as splices or grafts, Briggs. St. Louis Med. and Surg. Journal.
Eczema of hands, of face, McPhedran. Canadian Practitioner.
Ein Fall von spontaner perforirender Scheidenzerreissung mit vollständigem Austritt des Kindes und der Placenta in die Bauchhöhle, Genesung, Everke. Berl. Klin. Wochen.
Etude sur les principaux accidents de la chloroformisation à l'état normal, et dans quelques conditions pathologiques, Franck. Bull. de L'Acad. de Méd.
Epithelial cancer in a negress, Foster. Boston Med. Surg. J.
Empyema, Roberts. Amer. Pract. and News.
Extra-uterine pregnancy, occurring twice in the same patient, Meyer. Annals of Gynæcol. and Pædiat.
Ein Fall von Rhabdomyosarcom der Orbita, Zenker. Arch. für pathol. Anat. u. Physiol.
Eine Geschwulst der Schweissdrüsen (Cylinderepitheliom), Knauss. *Ibid.*
Emergencies demanding abdominal section, Sexton. Ind. M. J.
Etiology and treatment of migraine, recent observations in, Wharton Sinkler. Med. News.
Etiology in malarial infection and of the hæmatozoa of Laveran, G. Dock. *Ibid.*
Extra-uterine pregnancy, Bernardy. Ann. Gynæc. and Pæd.
Extra-uterine pregnancy, rupture of sac, laparotomy, recovery, Montgomery. *Ibid.*
Ensayo sobre los polypos laringeos, Budge. Rev. Med. de Chile.
Feigned cutaneous disease, Bowen. Bost. Med. and Surg. Jour.
False pregnancy, Madden. Amer. Jour. of Med. Sciences.
Ftisie miliara acuta san tuberculosa miliara acuta generalisata, Kalenderu. Clinica.
Fracture of the skull, Takaki. Sei-i-kwai Med. Jour.
Fibrous tumors of the pelvis, simulating ovarian tumors, Joubert, Medical Press.
Fracture of base of skull, aphasia, delusions, ultimate recovery, Norton. *Ibid.*

Address in Surgery.

BY LAWSON TAIT, F.R.C.S., EDIN.,[1]

President of Mason College, Birmingham.

SURGICAL TRAINING, SURGICAL PRACTICE, SURGICAL RESULTS.

MR. PRESIDENT AND GENTLEMEN: I do not know that there is any position in which one who practices the handicraft of surgery could feel a more weighty responsibility than that which I now occupy, and if responsibility is the best measure of dignity, I frankly acknowledge that there is no position in the whole wide world that could, by any possibility, be conferred on me which I should regard as a higher honor than that which I am about to try to fill worthily in addressing this great Association on the subject and object of my daily life. Your corporation now is but a short name for the profession and practice of medicine and surgery throughout the English-speaking world, and that means our globular part of the universe. There is no need for me to offer an apologia for our professional existence. From the earliest time of which we have any historic record—and we can even assert what I am about to say in some directions for prehistoric times—mankind has ever been earnest and selfishly sincere in his efforts to diminish suffering, to prolong life and to cure disease. Generation after generation has made fresh efforts of its best and greatest in such directions as these, and ever and anon fresh victories have been won. Now, as before, we represent the best and greatest of these achievements.

That we have made mistakes; that we have had to confess that our favorite theories, and some of our best established practices in one generation have become the flogging posts of the next, is but to confess that we are human. Nothing is human if it can have no progress, and progress is impossible in all human affairs without error. Even the most perfect of human sciences—mathematics—has had, is having and probably will have in time to come, its evolutionary stages. Even the apparently finite doctrine accepted unquestioningly for nearly two thousand years, that two lines which are parallel can never meet in space, is being shaken to its foundation, and those who can approach space from the aspect of its fourth dimension are staggered to find that the shortest road between any two fixed points may not necessarily be in a straight line. With such awful examples before us; with the fear that even the treasured first book of *Euclid's* propositions may prove to be a fraud, we who practice a mere handicraft, but one of the utmost importance to humanity, have need to walk carefully. It is not necessary that I speak for the importance and dignity of our work, for that is admitted on all hands, even with full knowledge of our shortcomings. Admitted it is to the full, for there is none unwise enough to avoid the counsel and help we can give him when the inevitable hour of trouble comes for his turn. The scoffer may be what he likes when he is well, but when the abscess pains or the tumor threatens, his tastes speedily become monastic. Humanity has on the whole a complete confidence in us, not that we are perfect, but as far as we are so approached we honestly do the best we can. It behooves us, however, from time to time to search out the innermost corners of our chambers, to rid them of all uncleanliness, and then to garnish them and to set them in order, hiding no blemish, concealing from ourselves even no defect, but striving in all ways to the perfection of that noble work to which we have set our hands.

You have already been welcomed to this great human hive in the words of our eloquent President, and I wish to re-echo his welcome because I have, for

[1] Delivered before the British Medical Association. Printed from advanced sheets.

once in my life, an audience before me worth preaching to, and I wish that my sermonizing powers were equal to the occasion. You have come to a great home of industry, the very paradise of the handicrafts. I wish I had the tongue of a William Morris to sing their praises, but as you go through our workshops, even those of the humblest kind, you will see such wonders as would empty from sheer exhaustion even his silver store. To look at the work, you may think that as little skill as exists in human sense would be required to cut an ivory nut into what they call blanks in a manufactory of buttons; but as you watch the patient workman for a few hours, and then think you would like to try to rival his skill, you take your place at the saw bench, and if you are not preternaturally skilful it will be only after sacrificing a few of your fingers that you find yourself behind him inexplicably in every conceivable way; you would then begin to have some slight appreciation of the skill he has acquired even in that small department of human art. You would then begin to appreciate the principle we all value here so much, for it constitutes the making of our factories—I mean the principle of the subdivision of labor. In such an apparently rough, and certainly very humble employment as that of the cutter of the button blanks, which I have taken as my text, a few questions will help us to much thought, and the answers may excite in many of us solutions for problems which are greatly exercising the authorities of our medical corporations at the present moment. You will find that even the cutter of the ivory nut will prove to be a more docile apprentice, and a more competent workman, if he has had a good education before he enters the shop, such an education as we supply now in our Birmingham schools, in a fashion compulsory and almost free. I wish it were entirely free. The philosopher who asserts that liberal education will spoil the future craftsman is a mere bookworm, without a true knowledge of human power. We further find that our button cutter must go through a long apprenticeship to accustom his eye to judge the nut, to avoid its faults, to accustom his fingers to the sense of resistance, and even his ear to the sound of the saw. Mere general education will do nothing of this kind for him, but the general training he has had will open his mind first of all to the sublime advantage of accuracy in all things, and it will make his mind just so much the more receptive for the monotonous details of his work. Finally, it will make him in all respects a better citizen than he would have been without it.

We may easily, and I think justly, apply these facts to the training required by our own handicraft of surgery. Every one has something to say on this subject, and I do not see why I should refrain from expressing my views, especially when I find that the general course of opinion is running at the present moment on lines on which my own has always lain. A surgical craftsman must be a trained gentleman, accustomed by a classical education to use his native tongue with ease and fluency and without confusion. He must have the fundamental principles of reasoning and of business habits instilled into him by such mathematical training as will be involved in his being able to pass some one of the ordinary examinations now insisted upon by all the licensing bodies. If he can spare the time and money to become a graduate in arts so much the better. Up to this point we are all agreed. Our apprentice surgeon has now to enter upon his purely professional training, and to learn the constituent parts of the body and their functions; and here comes in our first difficulty. I, for one, desire to raise my voice in protest against the absurd attention to detail and the enormous waste of time involved in the present biological training of the surgeon student. Let him be grounded in every fact of anatomy which may, under the rarest and most unlikely conditions, aid him to appreciate the results of an injury, or a displacement, or of a new growth; let him be grounded in all such items of information concerning the ultimate structure of organs and their mediate and immediate functions, and the changes to which disease subjects them.

Let him be placed so constantly alongside somatic sections that he will not only learn his anatomy, but that he will never forget it. Let him see things and think of them so often that he will, as it were, see through his patient as this man sees through his nut before he cuts it up. But I plead most earnestly that your successors shall be spared that senseless grind at useless details of anatomy with which our own young memories were burdened—details which he can remember only by a demoralizing system of catch words—details which he prepares himself to forget the moment the necessity of examination is over.

Still more strenuously I appeal that our student be altogether relieved from that senseless system of biological training which has set in as a fashion at Cambridge, at Oxford, and at Edinburgh. Not many years ago I attended a lecture on physiology given to medical students, which consisted in an explanation of a brass instrument resembling a model of Clapham Junction, intended to explain something about muscular fibre. I could not understand it, of course, I was too much of an old fogy, but I had this consolation, that when talking over it with my young friends who had attended the lecture with me, they could make nothing of it either, and it worried them as much as it had worried me. But there was a difference between us—it was demoralizing to them, for it discouraged them, and small wonder! And how angry they must feel when they come to deal with human patients and human disease, that all these nonsensical details are of no use to them—not even for the purpose of general training—when they find, in truth, that the time occupied in mastering such subjects has been absolutely thrown away. For students who are disposed to appear for a science tripos, or who have such a line of life open for them or the tendency towards it, who are possible professors of anatomy or biology, this kind of work is of course admirable; but of our medical students, nine hundred and ninety-nine out of every thousand will have to find their positions at the bedsides of their fellow countrymen in times of accident and sickness, and there such knowledge is useless.

I remember that we had to learn that the direction of the anterior cornu of the fourth ventricle of the brain ran a course which was backward, outward, downward, forward, and inward, and we were enabled in the most improper way to remember these important facts by the word "bodfi." Has "bodfi" ever served any of you at the bedside? Is there any conceivable condition of human accident or ailment in which "bodfi" could assist you to relieve your patient? The students who continue to learn such matters will find, as I have done, that they will be of no assistance to them to estimate the character of a delirium, and no amount of knowledge of the arrangements of the electrical currents in muscular fibre will help them to determine the proper relations of a splint. What I wish for our students is that they should go back to the institutes of medicine and leave comparative biology to those who may be able to benefit by it.

Again let me remind you of the terrible task that we had to fulfil in committing to memory the names and relation, the ligatures and points of contact, of the bones of the wrist and of the ankle-joints. To me this task has never served in the faintest instance. If, unfortunately, I had ever to submit one of my limbs to a joint amputation, I should most unhesitatingly insist upon the selection of that devised by Mr. Syme. The other more fanciful methods of amputation I believe are constantly condemned for very many reasons. Still, it may be that occasionally—perhaps ten times a year in the whole population of England—they are performed. For some specific reason they are not performed by surgeons in the country, distant from reference libraries and anatomical museums, and men who elect to perform such operations can in the course of twenty minutes, or half an hour, master the relation of these bones sufficiently to enable them to carry out the particular object they have in view. The question which occurs to my mind with great force is, Can the occasional performance of these somewhat eccentric proceedings justify the infliction of the senseless labor of committing all these special peculiarities of these bones upon every medical student who has to appear for examination? I cannot imagine that the committal to memory of these peculiarities can in itself constitute any kind of mental training, and I think the present system of anatomical education involves a gigantic waste of time and much frittering away of serious mental effort. As these words were gathering themselves in my mind, I turned to a number of the *Journal* which had just appeared, and therein I found a most interesting—I may say a most amusing—account of "Modern Assistants," by "A Sufferer," the sufferer in question being a practitioner who had, by reason of his work, to employ a recently qualified young man as assistant in his practice. In language far more trenchant than I can possibly employ, he gives a line of argument which I appreciate to the full, and he finishes what he has to say in these two noteworthy paragraphs:

"But no reasonable person can doubt the superiority of modern methods of training over old-fashioned ones. Our fathers made their apprentices pay them for the acquisition of practical experience, while we, more liberally, subsidize medical tyros to gain experience at our expense. Our predecessors thought that much could be learned of art and something of science in the surgery of the private practitioner, and by the bedside of his patients; we, more modestly, hold that the necessary science can only be taught at the hospital bedside, even when overcrowded by a hundred students, while art we practically ignore; but wisdom after all is justified of her children, and modern methods can proudly point to their resultant—the modern assistant. In face of such a practical proof criticism is silenced."

"'Of course you can vaccinate?' said a surgeon to a doubly qualified and newly-fledged assistant the other day. 'No, I cannot,' was the reply. 'Of course, I hold the certificate of proficiency in vaccination, but I never vaccinated a baby in my life.' Could anything be more entirely satisfactory and excellent than this, or more reassuring?"

In the old days—days which I can remember—it was charged against the corporations that they turned out a large number of ill-educated, empirical practitioners, who knew nothing but their patients. Now I say the tendency is to turn out a still larger number, a very much larger number of scientific young tyros, who know neither patients nor their disease till they have gone through a second pupilage, extending for years after they have left their university. This second pupilage lies in the rough school of experience, and in its second training they will be found deliberately and at once to throw overboard at least two-thirds of what they have learned in the first. What the boy wants after his general education has been fully developed, and his fundamental knowledge of useful anatomical facts and physiological principles has been made perfect to the utmost of their extent for usefulness, and not one scrap beyond that, is that he should be dealt with as we deal with the cutter of blanks in the button manufactory. He should be put at once into contact with his material. I, therefore, vote cordially with those who demand the restoration of the apprenticeship system in such fashion as modern requirements indicate. It is of course no longer to be a seven years' slavery in mixing pills and spreading plasters, for the modern manufacturing chemist does all of that for us now, but it should be a period of at least two years spent in learning how to deal with patients, how to divine their peculiarities, and in learning how to avoid making an ass of himself in the sick room as the modern, newly-fledged, qualified assistant is certain to do for the first few years of his second pupilage, in spite of his biological lore.

The road to success in the practice of our art lies not only in knowing how to deal with disease, but how to deal with men and women while they suffer from it. Our biological practitioners have no experience of either of these lines of research, and they, therefore, fail miserably. I had to meet a most excellent and estimable practitioner of the old school in the North of England some months ago, and he told me that within a year he had had three assistants, all Bachelors of Medicine and Masters of Surgery from one of our most flourishing biological schools. "Sir, would you believe it,". he said to me, boiling with indignation as he thought of the needs of his large colliery practice, "not one of them could put on a splint? and the third was such an ass that he used to lecture a collier's wife on how fishes lost their eyes in coal pits instead of supporting her perineum." I am speaking from a lamentable fullness of similar experience, and I feel that no other remedy is possible than which I recommend, and the sooner we begin to cry out for it the better. Our corporations are deaf to our appeals upon such subjects, because their rulers no more understand the requirements of the general practitioner than they understand the Confucian system of philosophy.

The Council of the College of Surgeons is directing its system of examinations more and more in the ultra-scientific direction, and the demand of the members of the College for a reasonable share of representation on the body, which at present is the great manufactory of general practitioners of England, is largely based on this preposterous blunder. As I read the questions put to the candidates at the College examinations, I wonder more and more how such a training as they involve can by any possibility suit men for the every-day work of country practice. The new scheme of the University of London, under which the new university will be largely constituted by the two Royal Colleges, will only go to perpetuate the mistake. With a spirit of selfishness which is inexplicable, this new institution is to be confined, so far as its government is concerned, to the eleven medical schools of the metropolis, including the School of Medicine for Women, and all discipline of education and control of examinations will rest in

the hands of our metropolitan rivals. There will be, therefore, a constant struggle between those outside the charmed circle and those within its pale; and I speak for those of us concerned, as we are here for a large and growing school, who will find ourselves greatly handicapped in the fight. But we shall not be easily beaten. We believe in teaching our students what they can best use when they enter upon the struggle for existence, and it is upon that kind of material we want to have them examined. We therefore propose to agitate, without ceasing, for a more direct representation of the body of the profession at those tables where the direction of medical education and medical examinations are controlled. Upon one point we are coming to an agreement, and that is a demand for the restoration of the practice of apprenticeship. But I would carry it further. While the student is attending to this most important part of his training, he ought at the same time—and now I am speaking for those who have to follow the craft of surgery—to be taught how to use his hands. I should set him so many hours in the week, into the shop of the village carpenter, and I should have him trained to use a saw, a chisel, a plane, and a skew; so that he should be able to make a long splint, if need be, as well as to put it on. And into the blacksmith's shop he should also go, till he knew how to strike properly with a hammer. Some of you may think this may be unnecessary; but, if you could look with a workman's eye (as I can do, for I served my time at the lathe, the bench, and the forge) at a Fellow of the College of Surgeons—I won't give his name, but you will find him in almost every large hospital in the kingdom—who used a saw for the first time in his life in the amputation of a human leg, and see, as I can see, what a horrible mess he makes of his work, you will agree with me that a training in practical mechanics is just as necessary (I say it is far more necessary) for a man who is to operate upon his fellow human beings as is a training in anatomy.

The great difference between the man who starts his saw cutting from the point of the saw and the man who starts from the hilt is just as great, I think it must be much greater than the difference between the man who amputates a leg without any kind of knowledge of anatomy and the one who has such knowledge fairly perfect. During the two years that our student spends in this practical training for his after-life, he would unconsciously imbibe the fundamental principles of the scientific training which he would afterwards have to undergo; he would see for himself, day by day, the characteristics of wounds healing healthily, and how different they are from those of a wound indicating action the result of constitutional poisoning. The meaning of these differences he would learn afterwards at his clinical school. At present he can babble about the theoretical causes of the changes, but of their real facts and phases of them he knows nothing. After his apprenticeship, as he heard in the academical rooms the explanation of the process of the healing of a bone, he could recall to his mind illustrations in the practice he had already gone through, and the combination of the facts as he knew them, with their explanation, would impress the whole thing on his mind in a way to which at present it is a complete blank. As a matter of fact at present in medical education, the cart is being uniformly put before the horse. Impressions in youth are far better and more lastingly conveyed by the eye than by any other sense. Words referring to clinical systems and to physical diagnosis which are now a mere shibboleth to the student, would, under better arrangement, possess a living interest, and what is used merely as dead rote for the purpose of passing examinations, would survive for his lifetime as the guiding principles of his practice.

Having now delivered my soul concerning the training which I believe to be essential for the craft of surgery, I fall naturally into the utterance of some words concerning the practice of the art, and I pause at the outset in absolute wonderment when I contemplate what has happened in my own lifetime. The year 1847 was the real birthdate of our work, when there first fell upon man that gentle slumber, anticipated in the beautiful legend of the Garden of Eden when Adam's rib was resected, but which was not brought into the region of actual fact till that memorable night in Queen street, when Simpson, Keith, and Mathews Duncan "were all under the table in a minute or two," to quote Simpson's own graphic description. What had gone before that time was mere groping in the dark, and what has happened since could never have been ventured upon but for that greatest of all human blessings—anæsthesia.

That has been to surgery what the motive power of steam has been for the arts, manufactures, and for commerce: it has revolutionized everything in connection with our art. And yet we are so accustomed now to take the advantage as a matter of course that we have almost forgotten its history. We are apt to ignore the fact that all our brilliant advancements of to-day could never have been arrived at but for chloroform—we could not have developed the splendid work of the modern ophthalmic surgeon, and the modern development of abdominal surgery would never have been dreamed of but for the genius and indomitable fighting qualities of James Young Simpson, who thrashed out the victory of anæsthesia and gave us the anæsthetic which for more than half a century has held its own against all comers.

This, the greatest of all medical triumphs, at once broke down the barriers which had hindered the development of our art, and a vast change in surgical practice became apparent. Not only were the horrors of the surgical theatre banished, but the type of men who could and did practice surgery was altered—in some instances though, not for the better. In the days before chloroform, the man who "niggled" over an operation was avoided alike by patient and doctor. A man like Liston, whose manual dexterity is said almost to have approached the miraculous, had it all his own way. Syme returned from London to Edinburgh for many reasons, but no doubt chiefly because his comparative defective manual dexterity was very apparent in contrast to many of those with whom he had to be in rivalry. He never could cut decently for stone to the end of his days, and but for the aid of the chloroform of his greatly disliked colleague, we never could have had the splendid philosophical principles of surgery which Syme laid down. He never could have been the surgeon he was, without the encouraging influence of an anæsthetic.

In fact, the history of this epoch of surgery is one of the most interesting there is, and I venture to say by far the most important. Indeed, it is only by reason that we are more or less all part of it that we do not see how overwhelmingly important the transaction effected in the years between 1850 and 1865 has been in the development of our art. In that time appeared men like Paget and Savory, who never could have been surgeons as Liston, Fergusson and Miller were, but who lived, and mostly are living still, to fill a higher and more useful post. They became the sur-

gical pathologists, among the first of whom in date we have to put Stanley, and now they are a goodly army. They have lifted us from mere handicraftship to something approaching a science—approaching the position of a science more and more every day.

But in addition to this, probably the best result of the change effected by anæsthetics, another of great interest arose about the same time. With the possibility of human benefit came a huge extension of the number of cases, not only of those suitable for the new work, but of those who could bring themselves to submit to it. Before the days of chloroform, vast numbers of men died of stone in the bladder rather than submit to the torture of the operation. Nowadays nobody is foolish enough to refuse to submit to the operation. Operationswere comparatively rare,and they were made the subject of vulgar theatrical display. I remember that when Syme had to tie an iliac artery or remove a tongue, he would have seven or eight hundred people from all over the country to "assist," as the French say, for only two or three could see what he was doing.

This strange perversion survives even to this day, and it makes me often sad to hear of the anxiety professed by many of my profession to "see" some great surgeon perform some big operation—an operation they themselves would never entertain a wish to undertake. Such performances, I think, ought to take place only in the utmost privacy and be witnessed only by such as can really be benefited by observing them, that is, men who wish to engage in operating practice and are likely to have fields in which to fulfil their wishes. Of course, there are some operations to be excepted from such remarks, and the real intention of what I have said must be clear enough to every one—for an operating surgeon to have a theater full of second year students, merely for the purpose of being able to say that they were in the same room with him, is a useless waste of time for the students, and for such purposes I wish all operating theaters were closed.

I have said the number of cases for operation vastly increased after the introduction of anæsthetics, and with this increase it became perfectly evident that no one man could grasp the whole realm of surgical work. The subdivision of the work became inevitable, and the best and first example of this subdivision came in ophthalmic surgery.

I have not asked Sir William Bowman, nor have I inquired of Mr. Anderson Critchett concerning his distinguished father, I have merely gone to the old medical directories for dates and I find the story told concerning these two men who were the first, as they remain still the greatest, of the pure ophthalmic surgeons we have possessed to be as follows: In 1850 Bowman was assistant surgeon to King's College Hospital, and assistant-surgeon at Moorfields; whilst Critchett was assistant-surgeon at the London, and full surgeon at Moorfields. Bowman left King's College in 1862, and Critchett left the London in the following year, after a very short tenure of the full surgency, and these dates are of the greatest interest, as they allow of just sufficient development of ophthalmic pathology by Helmholtz's great invention, to have persuaded both of those of whom I speak that their true vocations lay at Moorfields, where they both remained till 1877, and that they could not well combine rough general surgery with their finer work on the eye.

There are some of whom it would not be true, but as a rule it is now quite true, that a man to succeed in ophthalmic surgery, must practice it exclusively, and I fancy that any exceptions would go far to prove my rule.

In abdominal surgery nothing was really done, if we except the truly brilliant achievement of Ephraim McDowell, before the days of anæsthetics. It is true that in this country a few parovarian cysts were removed, and a still smaller number of very simple operations for ovarian tumors were completed; but there is little doubt that whenever any serious complication was met with, the abdomen was promptly closed. No solid tumor was completely and successfully removed till that now before us fell to the hands of my valued old friend, John Day, of Walsall, who was gathered to the majority only a few months ago. The greatest advance of all—the intra-peritoneal treatment of the pedicle by means of the cautery in the hands of Baker Brown, giving a mortality of ten per cent.—was the real starting-point of all our progress, and that proceeding would have been an absolute impossibility without the aid of an anæsthetic. Then came Spencer Wells, who, with his precise methodical plans and steadfast business-like habits, which have characterized all he has done, has established abdominal surgery as a distinct specialty. For this, as well as for much more, I and others owe him much gratitude.

As the practice of surgery has grown, so have the arrangements and provisions for its pursuit become enlarged and altered to suit the varying requirements. Great changes have been necessitated in our hospitals and in our medical schools, changes again to be traced directly to the inestimable benefit of anæsthetics. When I came to Birmingham in 1870 there was practically no hospital between Summer Lane and Stafford, or between Bath Row and Worcester. The towns round about us were supplied by old-fashioned dispensaries, where bronchitis was treated in the winter and diarrhœa in the summer. Serious accidents and important surgical cases were all jolted into the General and Queen's Hospitals. Old John Burton, of Walsall, aided by Sister Dora, had just begun to show, in 1870, what a cottage hospital could do. Now we have not only cottage hospitals innumerable, but we have palatial receiving houses for accidents and urgent cases at Dudley, West Bromwich, Walsall, and Rugby, and many other important centers. These local hospitals would do credit to any community, and the surgical practice in these institutions is quite brilliant, as many of you know. We have now in our midst a Hospital for Diseases of the Eye superior to anything of the kind, and its four surgeons, engaged exclusively in special work, are not excelled in the excellence of their results throughout the wide world. Not only so, but ophthalmic hospitals have appeared in smaller centers, as Shrewsbury and Wolverhampton, which have already acquired highly deserved reputations under the care of men who do not engage in special practice nor in general surgical work. A new feature has appeared at West Bromwich, for which I predict a rapid extension and splendid results. An enlightened committee has engaged the services of a special ophthalmic surgeon from a distance, at quite a handsome salary, to attend to their ophthalmic cases. The same committee has for many years engaged my own services for special cases, with the rank of consulting surgeon, but as the cases are few the handsome salary in my own instance is yet merely a prospect. In this same line another well pronounced division of surgical work has been accepted in Birmingham and the Midland district, of which you have heard something in another place from the lips of my highly

esteemed colleague, Dr. Savage. Here, more than anywhere, can be seen the triumph of anæsthetics, for not one of our modern advances could have been accomplished without them. Jean Louis Petit planned and described in detail the method of curing the troubles of gall-stone in 1745, but they could not be carried out till our patients were soundly under chloroform

The rearrangements of hospitals necessitated by the changes just described have had a most wholesome result on the practice of surgery. The crowding of our two large hospitals by cases of compound fracture and amputations has been sensibly diminished, and the cases are treated far more safely and quite as well in the cottage hospitals nearer the place of accident. The surgeons to our large hospitals are becoming much more of the special consulting and operating surgeons, and less of the senior general practitioners than they used to be; and in our smaller centers are being trained men competent in the highest degree to deal with the ordinary surgery of everyday life. In their turn these men are recognizing the advantage to their patients and themselves of yielding up the grave responsibility of special and exceptional cases.

By the development of specialism, and the establishment of a set of men in our midst who are not in any way engaged in general practice, I venture to think a great many advantages have been gained. Of this not the least is that the public derive what benefit consultation may give at the onset of their ailments instead of at the end, for I venture to say that nowhere now in this district are serious abdominal symptoms encountered without a speedy summons being sent to one of us who practice in that department; and it is in no small degree owing to the foresight and prompt action of our brethren who seek our help that we have the success which has crowned our efforts. Unless those who practice such a specialty have the confidence of their brethren by keeping clear of general practice, no such satisfactory results can be gained.

In dealing with the third division of my subject I have less clear ground upon which to go, and I fear I must depend more upon what I wish were the facts than upon what can be actually shown in their present existence. But I sincerely wish that we had better surgical results than we have; I wish we knew more exactly what they are; and, most of all, I wish that we could go about establishing them in a more logical fashion.

It has often been said that the greatest of the gifts of God which take the form of genius, I mean oratory, is the most potent of all for immediate effect, but most transitory for fame; and so it is with the sister histronic art. The dead printed matter (all that we have left of John Bright) gives not the slightest idea of the great artist he was. The phonograph may alter all this, and the orators of the future may enthral audiences as much as the skill of Leonardo captivates you in the Refectory delle Grazie at Milan, just as it could have done four hundred years ago. We have no such promise for the fame of the surgical artist, for he and his handiwork perish alike, leaving nothing but the bald and printed statement of cases. The limner's work lives almost for all time, and the sorrows of Ursula affect us quite as much now in the hospital at Bruges as when Hans Memlink first depicted them. We have only one comfort. In the days which Edward Bellamy predicts, and for which William Morris pines, the limner and the surgical artist will be the only highly paid craftsmen, for their art will remain something unapproachable by mechanical contrivance. This may be or may not, but it is a compliment of no small excellence that so great an authority ranks our craft so high.

In the results of our work we have much cause for congratulation, but I would rather look on the other side of the fence and wonder if they could not be improved, even with the methods we have now at work. For the last twenty years we have first been opposing a great theory, then we have been accepting facts on which it was based, then we have been rushing into violent and illogical enthusiasm about it, only at the end of all to throw doubt and dispute on the whole field. I confess I always doubt surgical theories, just as I doubt all theories of art. The greatest painters have been the least trenchant about theories. Turner never had a theory of any kind, and always used bad pigments; and John Brown tells us that Guido mixed his colors with brains, and could get no further explanation of his results. No school of art which started on a theory has ever made a lasting impression. The modern school of the pre-Raphaelites gathered adherents, it is true, but they have nearly all deserted their theories on finding that the Dutch school knew far more than they did; the Flemings had all their excellencies without falling into their errors. The Impressionists were similarly a failure. Our surgical theories never lead to anything; not even the great antiseptic theory has led to any tangible result beyond what every housewife knew before its day, namely, that dead moist organic matter will decompose if some agent or other gets to it. We know now the exact nature of this agent, but this is a new fact, not a new theory. The theorists forget that living tissue will not decompose under the access of the same influences—influences, indeed, which surround us at every moment of life, and pass by harmlessly. Now the theorists take a lingering farewell of their lost darling by saying, "Well, at any rate, it taught us cleanliness." As a matter of fact, the very reverse of this is true, for it was the arguments of those who opposed the antiseptic theory which demonstrated the successful cleanliness. The last phase of this discussion—I sincerely hope the very last—is the antiseptic accoucheur who pleasingly fancies that both his theory and his practice are new, whereas in matter of fact Semelweiss literally died for them nearly thirty years ago. No more instructive reading can be indulged in than a brief monograph which has recently been issued concerning the history of this truly great man—a man so great that I think he deserves to have erected to his memory a statue in every civilized country. Semelweiss had no theory, he simply stated the fact that puerperal women in Vienna were poisoned by dirt. "Wash your hands," he cried, "and the women will not die," and his colleagues ruined him for his frankness. But he persuaded the world he was right. Simpson took up the fight with his accustomed vigor, and carried it through, and now, forsooth, we hear of the antiseptic theory as applied to midwifery as a new thing.

What is wanted for the improvement of our surgical results is not any more theories, but better work and better systems of working, preceded by better systems of training. We forget that an art like surgery cannot be acquired by passing examinations. It is true that examinations admit to our academy schools in art, but they are merely for the purpose of selecting candidates upon whom it is likely that benefit will arise from the teaching which there can be obtained. Surgical art is not conferred upon the

successful candidates by the College of Surgeons' parchment for the Membership, still less by that for the Fellowship. Like all arts, surgery requires some indescribable gift, easily recognized and appreciated when seen, but wholly incommunicable by diploma or otherwise. With that gift the art may be acquired by persistent labor, but without the gift the labor is hopeless, and that this fact is being recognized in all our large centers of population, even in the close hospital corporations of the metropolis, is one of the most hopeful signs for better surgical results. Another hopeful sign is the demand for complete and accurate statements of results. Public attention is now being drawn very largely to the question of hospitals in general, and a most wholesome rivalry is being established upon the question of results ; so much is this the case that grave suspicions are being entertained regarding all institutions which neglect or refuse to publish their results. I remember very well that when engaged some fifteen years ago in writing a book on hospital mortality, I asked a large metropolitan hospital to furnish me with the facts of their amputations for a period of sixteen years. The hospital was notoriously reticent upon all such questions. The medical board answered my request by a resolution that it was not expedient to furnish me with the information required. I replied that if they did not furnish me with what I wanted within a month, I should publish their resolution in the *Times*, and, as this hospital was entirely dependent on annual subscriptions, they reconsidered their decision. Their amputation results were ghastly ; probably they did not themselves know how bad they were. Publication of these results had a marvelous effect, for now the same hospital has an amputation mortality of less than one-half what it was sixteen years ago.

To Sir Spencer Wells is most undoubtedly due the credit of putting the publication of surgical results on a business-like basis, and the extension of this ought to be encouraged in every possible way. When the results in abdominal surgery, which began to be obtained about twelve years ago, were first published, they were so amazing that the favorite criticism of them was that they must be lies—a complimentary method of criticism which, it may be mentioned, was meted out to Ephraim McDowell. This sort of thing at first was very irritating, and used to make me very angry ; but for many years past I have ceased to trouble about it, and the incredible things of eight or ten years ago are now matters of every-day experience. My present desire is to urge, in every possible direction, a careful classification and publication of surgical results as one of the best methods of improving them, for it is clearly necessary, first of all, that we should know what our results really are, before we can see the necessity for their improvement ; and, secondly, it is only by the comparison of the results from different hospitals and different surgeons that it is likely that we shall start rivalry and inquiry as to the causes of the better results.

Another great advance required is the divising of logical plans in recording and classifying the results, and also the adoption of reasonable methods of conducting the investigation. For example, no one would now, in making a research on the mortality of amputations, arrange his figures without a careful separation of amputations for accident, and those for disease, and a perfect arrangement of the cases according to the limb affected, and the point of amputation. But until Simpson pointed out the necessity for such divisions, the importance of them was not clearly understood, certainly was not fully admitted. Arising out of a matter so simple as this there are, there must be, scores of points which require settlement, yet no serious attempt has been made even to indicate what such points may be. It may be, for instance, that one particular method of flap making will suit primary amputation better than another, and a point so important could be settled in twelve months by a simple agreement amongst a group of hospitals and their surgeons. Let one set of men work steadily at one method for one class of cases, and another set at another method, and the statistical laws will be found faithful to the truth as they ever are when the figures are large enough. Instead of adopting a method like this, our present method is that when such a point is raised for discussion, surgeon after surgeon rises and gives vent to vague impressions which he is pleased to elevate by the name of opinions. The fact is that every one has been trying all the plans in a disconnected, illogical way, from which truth never can be evolved. One of the many things I admired about Tom Keith was the religious way he stuck to the cautery in treating the ovarian pedicle. Nothing could shake him. I was equally obstinate in my adhesion to the silk ligature. The result was that when we came to compare notes, after many hundreds of ovariotomies, we found that so long as the bleeding from the pedicle is effectually stopped, and the pedicle carefully dropped back into the peritoneal cavity, it does not matter a pin how it has been treated ; and that I venture to say is a surgical conclusion, not only of the utmost importance, but one which never can be contravened. The so-called discussion on special subjects, which are now fashionable at our annual gatherings, illustrate well how utterly futile our present method of research is. Take the case of the kidney. We have half a dozen men discussing such a question as that of removing a suppurating kidney, as a primary operation, or subjecting it to a preliminary drainage, and when you have heard all that they have to say, you are no wiser on the subject. But if four men would subject all their cases to one method, and four others would confine all their work to the second method, within five or six years the question would be definitely and finally settled, and the probability is that we should have determined, as a definite conclusion, that in all certain well-defined cases the best treatment was the first method, whilst in another class we should probably discover that the alternative was the better choice. The latest instance of this kind is the question of lumbar *versus* inguinal colotomy, concerning which I am certain that the shield has a silver as well as a golden side, and that our present method will never enable us to differentiate the two metals.

Some such plan of research as I have described would very clearly indicate in which set of conditions which proceeding ought to be adopted. It may be urged against my proposal that such a plan of research would hamper liberty of action ; but I answer that our present liberty of action is not wise—indeed, it is not liberty at all, but license.

Let me take a personal case. It is well known that I adopt a special method of treating uterine myoma, and that there is a rival in the field in the shape of the electrolytic method. It is a charge also against me that I will not try the electrolytic method—a charge to which I readily plead guilty, and for this conduct my defence is simple. I say that no logical and complete conclusion can be arrived at by everybody treating everything in every kind of way. Having opened out a continent, I want to know all about

it. I pursue, therefore, all the windings of its rivers, and I measure the heights of all its mountains, and I give you the results of my ten years' wanderings. Let the electrolycians do the same, and then you shall be the judges, not upon men, but upon principles. If the primary results of the removal of the uterine appendages are satisfactory enough to justify the experience being continued over an area of about four hundred cases, the judgment will rest upon the ultimate and permanent results. If the results of electrolysis are given with the same fullness and with equal authentification, and are found to be better than those of surgery, I have no more to say on the subject, and shall take a back seat. But meanwhile I am sure, in the interests of our art, that it is better that I should continue my research in a logical fashion, unhampered by qualifications which would make a just conclusion on your part an absolute impossibility, and which would lead to nothing in my own mind but confusion.

On the other side of this most important question lies another grave source of error, which is too true of our research into surgical results, though it is far more extensive in its results in general therapeutics in the practice of medicine. No sooner is a new drug placed on the market than everybody rushes to try it. At first all is well, and "rubbishin" is good for everything. Then come a few isolated hints about the "toxic effects of 'rubbishin,'" and finally "rubbishin" gets dropped altogether, and we hear no more about it. It is positively awful to think of what some of these new drugs—say chloral, for instance—may have done before they got settled. For the mischief that is done in this way the public is largely to blame, if indeed it is not wholly to blame; they like the idea of a new discovery, especially the upper classes, and I am told by men practising near the dwellings of the princes of the land, and at fashionable watering places, that the great burden of their lives is to keep up with the new drugs and the new dodges. People who live in such houses and such places always have a smattering of such things, and they judge a man harshly who is ignorant of them. For my part, I instinctively distrust men who are always going in for new drugs, and for myself I will have none of them. In our surgical results there is too much of the same thing. Take the case of Dieffenbach's operation for squint, a most useful proceeding judiciously applied over a limited area. But I remember the time when every urchin with a squint was collared in the street and walked into the operating-room to have one rectus divided in order that its opponent should have full power to swivel the eye out in the opposite direction. Everybody was "doing squints." Similarly, when removal of the uterine appendages was proposed, but long before the just and true principles on which it is now based could be formulated, everybody rushed into the trial of it, and the result was a disastrous epidemic, the chief burden and discredit of which fell upon me.

I was more horrified than I can tell, and much of my time was taken up in disclaiming the doubtful honor of what was called "Tait's operation," in the performance of which every principle advocated by Tait was neglected or deliberately outraged. If the men who engaged in this work had waited for a reasonable trial, a fair discussion, and a just verdict, much discredit for our art would have been spared us. The just verdict has now been arrived at, and the misrepresentation, of which this operation was the center, has now ended. But the example is a very telling one in illustrating the want of logical application in our present method of research upon surgical results.

This vast and powerful Association could accomplish almost anything it wished after determining that it was for the good of the world, and after a reasonable method was pointed out for its accomplishment. We tried an expensive experiment in the way of a collective investigation, but from intrinsic reasons it was a failure. The fact is that its plan was lost in diffuseness, and defeated by the machinery involving a vast number of contributors—in fact, to increase the means of success involved the very essence of increase of risk of failure.

If you want a thing done well, you must either do it yourself or trust it to a very small number of workers. I do not think it would be too much to ask our Association to do to place every new drug and every proposal for a new surgical proceeding under the observation of a small responsible committee, whose judgment should precede anything like a wholesale experiment by the professional public at large. This step, which, to some extent, has already been taken in the formation of a Therapeutic Committee, might, with advantage, be extended to surgical proceedings, and would certainly clear away a vast amount of rubbish, and would direct more extended research into definite lines, instead of the indefinite and hap-hazard roads it now runs upon in almost every instance. And I cannot help feeling it would prevent us doing the great deal of harm which is now done in the early stages of even our best proposals.

My proposal may be crude and unpracticable. It may be easily perhaps displaced by some other and better. But if I have only imbued you with the necessity for reform I have gained my end, and shall have accomplished the object of this Address in Surgery.

INEBRIETY IN AMERICA.— HISTORICAL FACTS RELATING TO ITS STUDY.[1]

By T. D. CROTHERS, M.D.,
Sup't Walnut Lodge, Hartford, Conn., and Editor Journal of Inebriety.

I PROPOSE to give a general outline of the most significant facts apparent from a review of the present state of this subject. The term inebriety is used in its broadest sense to express all forms of excess from the use of alcoholic drinks. In America inebriety comes most frequently from three distinct social classes. The first use wine and spirits regularly at the table, as tea and coffee are used, and become inebriates from physical and mental shocks, strains, sudden depressing emotions, severe exhaustion illness or injury, etc. The children of such persons are always more likely to become inebriates. The second class are born of weak, diseased parents, brought up in bad surroundings, where every impulse is unhealthy and perverted, and alcohol is familiar to them from childhood. A third class are temperate up to the time of entering into business or the active duties of life, then from special cause become moderate drinkers, and later are inebriates. They may be temperate half a life-time, then suddenly develop inebriety. Heredity is most marked in the first class, and is always a sign of physical and mental degeneration in the second class, while the third class are most frequently the outgrowth of habitual neglect of healthy living and general exhaustion of all the func-

[1] Read before the London Branch of the Brit. Med. Ass'n.

tional activities of the body. Dipsomaniacs come in the first and second class, and the steady and irregular drinkers are found in the last class. The exciting cause is very often imperfect nutrition and want of rest; in others, psychical states of depression and exhaustion, from many causes, precede the drinking. These conditions can be traced, and are often clearly outlined in many instances; in others they are obscure. Inebriety in America is more impulsive and precipitate than in other countries, the period of moderate drinking is less marked, and the average life of the inebriate is shorter. Among the many reasons for this are the tremendous activity and competition in the ordinary work of life, the intensity of living, the constant excitement and changes, filling every moment of time, calling out every energy, putting them in a constant strain, followed by want of rest, neglect of the healthy functions of the body, etc., etc. Add to this the constant practice of using the strongest alcohols at all times and occasions, and it will be seen that the average American must of necessity possess less resting power, and will fall a victim more readily to the action of alcohol.

The effects of these influences are marked psychologically in the character of the inebriety seen in America. When under the influence of alcohol the average American is full of delusions of speculation for wealth, power, and political achievement; his ideas flow in a channel of great events, and great schemes for the welfare of the nation and the races; he is rarely a wife-beater or avenger of personal wrongs, but may be prominent in a mob to destroy some great evil, or foremost to break up some old order of events which are supposed to be blocking the wheels of progress. The inebriate American will always be found in the van of every new project in politics, social science, religion, and business, and, like Col. Sellers, is buoyed up with the stimulating hope of "There's millions in it." The records of courts rarely exhibit brutal crime among inebriates who are Americans, but great schemes of companies, frauds, and stupendous swindles, for money or notoriety, etc., etc., are common among this class. The increased consumption of all forms of alcoholic drinks, which is far beyond the average gain of population, gives unmistakable indications of the rapid increase of inebriety. This is confirmed by the courts' records of drunkenness in all the large cities and towns, and also from comparative evidence of the mortuary statistics which point to a rapid increase of these diseases which are most common in inebriates, namely, insanity, paralysis, and acute affections of the heart, kidneys, and lungs. It may be said, beyond all doubt, that inebriety in America terminates most frequently in acute organic affections of the body. Another fact of great interest is apparent to the psychological student, namely, that inebriety in America moves in waves and currents, with a decided epidemic and endemic influence. This can be traced to the rapid increase of drunkenness in towns and cities, and after a time a reaction sets in, and a marked decline follows; the latter is seen following the temperance agitation and revivals. In some cases this is traced to special causes, such as financial depression, great social changes, etc.; at such times moderate drinkers become pronounced inebriates, and weak, nervous organizations fall into inebriety. This increases up to a certain point, then from some unknown psychical force declines, and a revival of temperance efforts follows, with a decline of inebriety to a minimum. These waves and inebriate storms that sweep over large circles of country, are always followed by intense revivals of temperance interest, and are fields of the most fascinating psychological interest yet to be studied. Inebriety among American women is unboubtedly becoming more pronounced every year. Although it is more covered up than in other countries, yet its increase is apparent in the great demand for narcotics, and the sale of beer and wine by grocers; also in the divisions of saloons into general and family entrances, with separate rooms for each. Among the better classes of women, wine and spirits are less openly used, and social drinking more rare. The same is true of all classes except those of foreign birth, who still cling to the old custom of public drinking. The same general causes govern women that are noticed among men, only varying in degree; hence, while women do not use alcoholic spirits as men do, undoubtedly they consume all forms of narcotics in excess of other classes. Their peculiar sensitive organization demands narcotics as a relief from the strain and exhaustion to which they are constantly subjected, and this is a source of great peril to the future of the American race.

In this brief outline of the nature and character of inebriety, it may be said that American inebriety is more often a pronounced form of brain and nerve degeneration, and that it comes from well marked physical conditions, largely controlled by social and psychical states peculiar to America. Its symptomatology more nearly resembles that of insanity and general paralysis; its course is in waves and currents; its progress is shorter; and among women the use of narcotics is more prevalent than of other forms of alcohol. A history of the study and means used in the prevention of inebriety would fill a volume, and be of intense historical and psychological interest. It will be found to follow the lines and history of every scientific advance, passing through the same successive periods of credulity, superstition, inquiry, and acceptance as actual truth. I shall, in this brief sketch, group some of the leading facts under two heads, viz.: *The empirical, legal and moral stage of the history and the rational and scientific period.* The earliest organized effort in modern times to prevent inebriety, was a temperance society which began in New York State in 1828. The object of this society was to aid others in pledging themselves to abstain from all use of spirits, and help each to carry out this resolution. From this beginning have come all the varied temperance societies which at one time or another have been prominent in nearly every city and town in the country. The growth of this movement has been wave-like, appearing at times very prominent, and extending over the country, enlisting all classes for a season, then dying away. The Washington societies began in 1840, and in two or more years numbered many thousands among it members, but were, ten years after, practically unknown. These organized efforts, now seen in one form, then in another, have been gradually growing into more settled methods and on better plans of action. The churches have taken hold of the work, and, upon the theory of vice and sin, denounce the inebriate as a sinner, who prefers to drink and do wickedly rather than be temperate and live a Christian life; from this they have urged, as the only remedy, prayer, conversion, and a religious influence. Great revival movements based on this theory called "Gospel temperance work," have swept over wide sections of the country, creating much excitement. States and districts have been divided up and workers sent to make a thorough canvass of each section, holding meetings and urging all to sign the pledge and abstain from the use of spirits. Some of these temperance societies have very systematic organizations extending over many

States, with national councils, corps of lecturers, society papers, and large volumes of transactions. The prohibitionists, or those who would stop the sale of spirits and increase the punishment of those who use it to excess, urge that it be made a political issue, and enforced by laws. They are sanguine that this is the true remedy to remove this evil. All of these society efforts fail to work harmoniously to one end; hence their labor is not productive of results that last. One reason for this diversity is said to be the growing conviction that the temperance question will enter into party politics in the near future, then the struggle will be between these varied organizations for recognition. Within a few years all these and other labors in this direction have become very active, and now nearly all the Legislatures of the different States are urged every session to enact laws controlling the inebriate and the sale of spirits; also great summer mass meetings are held to urge the people to sign the pledge; church conferences devote days to the consideration of the subject. These are only general outlines of the work to-day in America, which, is growing more intense and active. It is clear to all who look over the field, that this is especially a period of agitation, from which the real work will by-and-bye emerge, along lines entirely different from that seen at present. A glance at the literature will show the same ephemeral and transitory character. At first, papers, tracts and sermons of an exaggerated sensational character, then gradually these are replaced by facts and arguments which come in the province of every one to determine. As the subject became better known, efforts to educate the public in regard to alcohol and its uses or abuses have followed. To-day the publication of a number of semi-scientific works devoted to alcohol and inebriety is a promise of great significance for the future, although some of these publications are dangerous because of the half truths they contain, from which conclusions and inferences are drawn by the reader which a better knowledge would dispel. Large publication houses are devoted exclusively to temperance literature, and issue great numbers of books, magazines, papers, musical works, etc. It may be said that in no other country is there so much printed matter relating to inebriety coming regularly from the press. Nearly every society and church organization is full of enthusiasm to create public sentiment by the printed page, as well as by the public lecture and sermon. The value of these means can be estimated only in the most general way. The fact of inebriety steadily increasing indicates clearly that no direct results follow these efforts, and that only in some indirect way, not clear at present, can these means lessen inebriety and save the drunkard. A study of the local influence of this temperance work in several communities will furnish some light or explanation why it is not more effectual all over the country. Here it will be found that the means used are addressed almost exclusively to the emotional side of the inebriate; that appeals to his reason, pride and religious faculties are very often sources of irritation and exhaustion, permitting no rest to the emotional nature, and by trusting to glittering hopes not founded on physical states, the failure is always followed by reaction and loss of nerve force, making the last state worse than the first. Also it will be apparent that a certain number of persons will become profoundly impressed by the means used by societies, and take on a condition which may be termed *psychical shock*, in which they will remain temperate ever after, on the same principle that a certain number of cases will recover from the apparent application of any remedy, no matter how absurd. In cases of fever a certain number will recover by the application of the pledge and prayer; but no data could be drawn from this to warrant the general use of this method in all cases. The conclusion is clear that a prominent cause of the want of results from the varied temperance labors is that the means used are not adequate to the end sought; hence, cannot lessen inebriety or reform the inebriate, for the reason that they are not along the line of nature and its fixed laws. The *legal methods of curing inebriety* by *fine* and *imprisonment* are universally acknowledged, by all who have made inquiries in this direction, to be failures. The punishment of an inebriate by placing him among criminals, in bad physical and worse mental surroundings, in which nothing but alcohol is removed, in a large majority of cases, precipitates him into chronic stages, and removes him farther from hope of recovery. Of 1,000 commitments in New York City for inebriety, 936 have been sentenced before from 2 to 28 times. In the city of Albany, in 20 commitments for the first time for inebriety, 14 of this number were repeatedly returned for the same cause during the next five years, 2 died and 4 were lost sight of. Officers of jails and prisons and magistrates of all district courts are united in condemning the legal methods of suppressing inebriety. But they are powerless to change these methods. The very object and purposes of the law are defeated, and a class of incurables are raised up that are a perpetual menace to all law and order. The value of total prohibition enforced by legal measures is yet on trial as a practical measure for the cure and prevention of inebriety. In some States its workings are said to be very encouraging. How far the legal restriction of sales can break up inebriety must be determined in the future. It is clear that this and other measures for the benefit of the inebriate can be more thoroughly tested in America than in any country of the world, because society is less fixed and more flexible, and the application and indorsment of practical measures are more readily entered upon than in other communites.

The second period—the rational or scientific epoch—began in 1790, when Dr. Rush, a distinguished physician of Philadelphia, urged that inebriety was a disease, and should be studied and treated as such. He affirmed that it was a physiological and not a moral condition. This was not a new idea, but had been mentioned in a very early age of the world, and had been repeated from time to time all along down the ages. Forty years later the same views of Dr. Rush were repeated and urged in some detail, bringing out many angry responses from clergymen and temperance advocates. In Europe this theory was taken up and made the subject of several papers which have become historical. The idea was repelled by the moralists as a cunning excuse to cover up the wickedness of inebriates and as contrary to the teachings of the Bible.

Nothing but discussions followed until 1852, when Dr. J. Edward Turner projected the first asylum for the medical care and treatment of inebriates, which was subsequently located at Binghamton, N. Y. Ten years after a large, beautiful building was erected, and patients received. In 1859 a similar asylum was begun in Boston, which is now the famous Washingtonian Home. The asylum at Binghamton early fell into the hands of incompetent and dishonest managers, and became a center of political intrigue. Both the income from patients and State aid were large, and, after a checkered career of fifteen years, it was

turned into an insane asylum. The legality of this is to be tested in the courts, with a good prospect of restoring the building to its original design or purpose. During the fifteen years as an inebriate asylum about 7,000 patients were under treatment, and from the study of over 2,000 cases, five years after the period of treatment in the asylum, 62 per cent. were found to be temperate and sober. When the difficulties of this work are considered, with the extreme chronic stages of the persons coming under treatment, and the inexperience of its managers, this result is a most significant promise for the future. Psychologically it very clearly repeated the history of every new advance of science. First, in the extravagant enthusiasm and expectation which attached almost miraculous power to the asylum and its appliances; second, when the truth dawned on the minds of these enthusiasts that inebriety as a disease could only be cured by long and exact processes of physical means accurately adjusted to the special needs of the patient, a reaction set in, and a great army of skeptics and doubters sprang up. This class, who are ever seeking the mysterious, have organized asylums in different parts of the country, which, while acknowledging the needs of restraint, deny the notion of disease, and urge that faith and conversion are sufficient for all cases. Three or four of these asylums have attained respectable proportions in size of building and number of inmates. Several asylums were organized in the interests of politics and rings that, after a few years, were abandoned as failures. Others have been founded on broader principles, where the physical nature of inebriety has been recognized, and means and remedies sought to meet this want, and, although opposed very sharply on all sides, have gone on quietly building up and demonstrating these facts. There are over thirty asylums for the treatment of inebriates in America; some of them are small and empirical in their theories, and many of them are broadly scientific in plans and appliances. All of them suffer from want of legal aid to restrain fully such cases; also, from innumerable obstacles and want of knowledge of those cases, and the best means of treatment and aid to carry it out practically. Also, the fact that a vast majority of such cases are chronic, and more or less incurable before they come for treatment.

Everywhere these asylums are building up public sentiment in the direction of physical means and methods of treatment. Although the question of moral means and the vice of inebriety are still discussed, yet a conviction is rapidly growing that many of these cases of inebriety are diseased, and require actual restraint in asylums. Radical temperance societies urge this view in many cases. This is seen in the coffee-rooms and temperance eating-houses under the care of societies, where rooms are provided, and temporary shelter for those who, with out homes, sign the pledge and make an effort to reform—a clear recognition of the value of positive physical means in the treatment of these cases. Without doubt the evils of inebriety are more generally recognized in America, and in many ways more money and efforts are made to remove and remedy this evil than elsewhere.

To the careful observer, through all this confusion of theory and effort, there are unmistakable signs of a new era, and a wider and more thoroughly-practical knowledge of the means and remedies that will cure this disorder. The first effort to group and study the facts as they appeared from a scientific inquiry began in 1870, in the organization of the "American Association for the Study and Cure of Inebriates." This association is made up of physicians who are connected with inebriate asylums and others interested, and is based on the general principle that inebriety is a disease, and is curable as other diseases are. To this end asylums are essential, or special and particular quarantine stations, where the victim can be housed and given exact physical care until the causes are removed, and the patient built up into a more healthy condition of living.

This association has continually urged that inebriety should come under medical care in special hospitals, and that the victim should be held responsible —like the small-pox patient—to use every means for recovering; that the State should see that he is isolated and properly treated for this malady; that the best methods of treatment can be found in work-house hospitals, where occupation, combined with the best scientific and sanitary surroundings, shall make recovery a matter of much centainty. The opposition urge that this theory is dangerous to the inebriate, and encourages a reckless disregard of his personal obligations; also, that asylums are of only limited value for the first few days, or until the spirits are out of the patient; then the pledge and power of faith can do more than all other means. This view of inebriety is urged only by those who are practically unfamiliar with the natural history of the inebriate, and does not grow among thoughtful students. To the "Association for the Study and Cure of Inebriates" is due, very largely, the growth of the scientific inquiry. Its transactions and journal have been going out regularly to all parts of the world, and its papers (many of them by the most distinguished physicians) have exercised a very wide influence in forming correct sentiment concerning the inebriate and his malady. One of the results is seen in the number of asylums being built in different parts of the country. In several States appropriations have been made, and State institutions have been projected. Many private corporations have buildings in course of completion, or in active operation, receiving patients. It is apparent that public sentiment is rapidly turning to the physical side of inebriety, and the theories which prevailed as to its nature and treatment are challenged and questioned before acceptance. The time has come to demand the facts above all theory, and to insist that inebriety be studied and treated as a physical state, not a spiritual nonentity. A feeling of alarm pervades public sentiment; the calamities following and associated with inebriety seem to peril all progress and civilization, and the inquiry, What can be done? is heard from all sides. The conflict and confusion of fact and theory, now gathered about this subject, is the sure promise of the speedy dawn of a scientific study and exact knowledge of the nature, causes, and treatment of inebriety. As a summary of the above, the following will serve to bring out the facts more clearly:

1. Inebriety in America is one of the greatest sources of peril to civilization and progress. It is very pronounced as a disease, and can be often traced in waves and currents, where the causes are unknown.

2. All efforts to remedy inebriety by moral means have failed; although applied with great fidelity and enthusiasm and ample means, yet inebriety has notably increased. The present labors of both men and societies along the moral side of this subject are evidently nothing but agitations, whose real value is simply to call attention to the evil.

3. Inebriety, when studied from the side of science, even in the most superficial way, appears as a great

physical disorder following a line of law that may be seen and understood, the practical application of which promises the most satisfactory results.

4. Inebriate asylums, as stations where the inebriate can be housed and studied, are necessary means for the cure and restoration of the inebriate, along the line of natural laws; and their practical value is assured beyond all controversy and doubt.

5. Inebriety in America, as elsewhere, must be studied above all theories and dogmas before it can be known or understood. The inebriate is no exception to the vast armies of defective or degenerate, who appear everywhere as the result of violated law and physical conditions of life and surroundings.

MODERN PHARMACY CAN SATISFY THE REQUIREMENTS OF MODERN THERAPEUTICS.

By PURNELL F. SAPPINGTON, M.D.

IT is not the writer's intention to criticise the excellent article by Prof. Woodbury, but simply to reply to some of the ideas he has mentioned.

Every workman should know how to handle tools, and to be able to distinguish good from bad. This, unfortunately, is not the case, if physicians are the workmen, and drugs the tools; for few, indeed, could tell what would be the result of morphine and tr. iron in combination. Good tools can be obtained at the drug stores; but can the doctor distinguish good from bad? Patent medicines undoubtedly detract from the scientific standing of the apothecary, yet a still greater detraction is the prescription calling for A, B, or C's preparation, all of which have a printed formula on the label, and give the dose which the physician is instructed to prescribe. Are these remedies ever analyzed by the men who prescribe them? Would it not be better if the physician's idea of the materia medica were large enough for him to depend on his knowledge to write his own prescriptions and send them to a capable druggist? Are not these physicians often disappointed when they order any of the printed formula articles? And when the effect is not produced, do they attribute it to the fault of the compound, and cease to prescribe it, or do they think they have erred in their diagnosis and prescribe another? This should be taken into consideration when they prescribe a legitimate prescription which fails to do the work for which it was prescribed, and all the blame should not be attached to the druggist. Surely, the druggist is as worthy of consideration as the compounder of the advertised articles. A physician has as much right to specify the druggist to whom the prescription is to be taken, as he has to prescribe A, B, or C's preparation. Does he not reflect on the capability of the druggist by prescribing any of these?

The idea that physicians have no interest in the Pharmacopœia is the result of just such prescribing, as the formula-printing manufacturers can compound labels to suit the taste of the great number of physicians, who accept on faith the circular which claims for the remedies curative powers for all the ailments which affect the human race. The keynote of scientific pharmacy is undoubtedly the standardization of articles to be dispensed, and if laws were stringently enforced on those druggists who dispense articles not standard, it would indeed be a great desideratum.

Who is to be held responsible when a pepsin is to be dispensed—the doctor, druggist, or the stomach of the pig which refuses to give it up? Pepsin has never been isolated, and yet how many thousand times is it prescribed in a day. If a druggist knew that a physician would know just how his prescription should look when finished, he would not dare compound it incorrectly; but when such prescriptions as the following are brought to his shop, signed by leading physicians, what else can he think but that the rudiments of chemistry are unknown to their authors?

℞.—Pepsin purè (Fairchild's) . . . . . ℥ij
Syr. simplicis . . . . . ℥ij
M.—Sig.—℥ss every four hours.
[Signed] ——— ———

℞.—Ol. morrhuæ . . . . . ℥ij
Syr. ferri iod. . . . . ℥ij
Syr. prun. Virg. . . . . ℥j
Muc. acaciæ . . . . . q. s. ℥iv
M.—Ft. sol. Sig.—℥ij every four hours.
[Signed] ——— ———

What is he to say when the woman returns with the first, and says it smells so bad that the baby, young as it is, cries when the cork is removed? and what must he think of both of them?

The remedy is to have a compulsory course of practical pharmacy in the medical schools; then, and then only, will prescriptions and medicines be all the most exacting can ask.

The Polyclinic.

PHILADELPHIA HOSPITAL.

W. E. Hughes, M.D.

PLEURISY.[1]

I WANT to ask your attention to a post-mortem examination that was held on a patient who died of pleurisy, in which there was marked effusion. The man's history was negative and he was always healthy, but not robust. He came to the hospital on January 12, 1890, and the physical signs on examination were those of an effusion in the right pleura. His temperature was decidedly above normal, but soon after fell to normal, as is the rule in such cases. After a few days he was aspirated, and forty-eight ounces of clear serum taken from the chest. This had no perceptible effect on the temperature. In the course of a few days the effusion began to accumulate and the temperature began to fluctuate, with a tendency to be higher than it was. He began to lose flesh, and coughed a great deal. He was aspirated again and clear serum was obtained. Both of these aspirations were done on account of dyspnœa. Following this his side and right side of the face became œdematous; he perspired freely, and developed a hectic appearance. Under thorough antiseptic precautions he was tapped again, with the hope of finding pus. A thick, viscid pus, with some bubbles of air in it, was found. The air could not be accounted for by any leakage in the pipe of the aspirator. Forty-eight hours afterward he developed a distinct pneumothorax. Marked tympany on percussion; amphoric resonance on coughing; bell-like sound and a succussion splash. One hundred ounces of stringy pus was taken out later. Before this last tapping there had been a marked communication between the bronchi and chest cavity. In the second right interspace there appeared a subcutaneous em-

[1] Reported by W. B. Stewart, M.D.

physema a few days after the pus had been withdrawn. He died a few days later and a post-mortem was held.

The right lung was found collapsed and bound down to the chest wall by bands of lymph. It contained no tubercles that could be detected. It is the ordinary lung found after a long continued immersion in fluid in the pleural sac. Thus, you see, there is a danger in allowing the fluid to remain too long. At the seat of the subcutaneous swelling was found an abscess cavity filled with pus and air, and was just about ready to emerge through the skin and establish a communication between the pleural cavity and the air. There was a little button-hole cavity between the fibers of the intercostal muscles. From the fact that he had been in the habit of taking cold easily; from the pleuritic effusion on the right side and the dry pleurisy on the left; from the fact that there was such a tendency for the fluid to reaccumulate after tapping, I was led to think there might be a tubercular infection, and I was confirmed by finding the left lung studded with small tubercles. Occurring as it did in a person with a tubercular tendency, and on both sides, gave the suspicion that it was tubercular pleurisy. As to the purulent effusion, I think that the tapping and the tubercles had nothing to do with it. Here I think there was an unfortunate accident that was not due to the treatment. In the first place, there was a perforation of the lung, and this is one of nature's attempts at a cure. The other attempt of nature has been the perforation through the chest wall in the second interspace, near the sternum, on the right side. A perforation here would not do him any good, for it is too high up to permit of drainage. About the fifth interspace, close to the sternum, is the most common point of perforation. If we resort to the same measure by artificial means we can aid nature. This man's condition was such that it did not warrant this procedure of putting in the tube to give free drainage.

PERNICIOUS ANÆMIA.

The next patient is an old woman, aged seventy-five years. Her mother died of phthisis. She has always enjoyed good health until five months ago. During the past five months she has suffered from diarrhœa, and feels wretched and miserable; has no appetite, and is troubled with paralysis agitans. She is distinctly anæmic, and she has developed this muddy, earthy appearance. Some time ago she had a peculiar lemon hue. Looking at her lips you can see the anæmic pallor. Her tongue is coated. Anæmia is a symptom of almost any chronic disease, and, when we find a patient with distinct anæmia, we believe there is some cause. In this woman's case all her organs have been examined and no abnormality nor morbid growth could be detected. The diarrhœa was not sufficient to account for the anæmia, but is rather a consequence of it. When you have a case of anæmia as intense as in this woman's case, you should examine the blood. Such was done here, and the red cells were found to be 902,000, in place of 5,000,000. The red are less than one-fifth of what they should be. Hæmaglobin is 20 per cent. of normal. The corpuscles are slightly irregular, and a few microcytes, larger than normal, are present. There is no considerable poicolocytosis.

We have in this case an anæmia without an apparent cause, which was attended originally with little waste of tissue, so that, with all these elements enumerated, I think we are justified in giving a diagnosis of pernicious anæmia. There is a class of anæmias that are not due to any demonstrable cause, unless it is due to the blood-making apparatus. We have leucæmia, hydræmia, pernicious anæmia, chlorosis, and Addison's disease, all connected with the blood-making apparatus. In this case we have an essential anæmia and not leucæmia or chlorosis, that do not occur at the age of seventy-five years. There is no bronzing of Addison's disease; no enlarged glands from Hodgkin's disease. You must also distinguish and diagnose all cardiac diseases that will often cause trouble of this kind. A distinct functional murmur is heard at the base of this woman's heart—soft, and not transmitted. There has been no nose bleed or hemorrhages. In some of the cases a distinct change of marrow in the long bones is found; but this is not at all constant. There are some cases of pernicious anæmia where there has been almost complete atrophy of the secretory elements of the stomach. I think there is something of this kind in this case, manifested by the impaired digestive power and diarrhœa. The prognosis here is bad, but there is still some hope of recovery.

In this same connection, I wish to show you another woman who presents a similar condition of affairs. A few weeks ago she was a good picture of marked anæmia, and still is more or less anæmic. She is forty-nine years old and has passed her climacteric. Sixteen weeks ago she was in good health but was seized with an attack of pneumonia on the right side, associated with jaundice. She recovered but never regained her strength; got weak; had pains over her body; appetite poor; extreme palpatation, and could not sit up. Examination of the blood showed 1 800,000 red cells; hæmaglobin 45 per cent.; white cells not increased; blood cells normal in shape. I present this case to show you what can be done towards a cure. She was given arsenic, which was gradually increased so that she took fifteen drops of Fowler's solution three times a day. Her color has become better and the symptoms have been ameliorated, and, instead of lying in bed, she is now able to go about the wards and do a little work. This is one of the curious things about pernicious anæmia, for you can produce good results in three fourths of the cases by the use of arsenic. It is not necessary to use it in particulary large doses, but in this case I have run the dose up. I have obtained excellent results from five drops of Fowler's solution three times a day, and it is *the one remedy*. I recall a case of five years ago, in which the corpuscles were only 500,000 in number, and in one week's treatment with arsenic the corpuscular value was normal.

In addition to this, take care about the diet. Oftentimes a change of residence from a malarial neighborhood, will do much toward a cure. If digestion is weak, as it usually is, give light assimilable food, and if necessary, resort to rectal al mentation. Rubbing into the skin hot cod-liver oil, or sweet oil is valuable. As to other medicines than arsenic, little good is to be obtained, unless you want to meet other conditions. Iron has little effect on pernicious anæmia, but its use is valuable as a point in making a diagnosis. In chlorosis you must give the patient as much iron as can be borne.

Are the results obtained in the treatment of pernicious anæmia permanent? I think that all the cases I have been able to follow up have relapsed, and it is necessary to gain the full confidence of the patients and keep them under treatment with the hope of an ultimate recovery. The first change in the blood, as a rule, is an increase in the number of corpuscles, and not an increase in the hæmoglobin.

OREXIN.

BETWEEN the interested encomiums of the proprietor and detractions of his rivals, the fortunes of newly introduced remedies are somewhat precarious Men have learned to doubt the exaggerations of the former, and, as the conscientious practitioner dislikes to experiment with uncertain agents when he has already remedies with which he is familiar, the chances of success are rather against the newcomer. Nevertheless, it is well worth our while to keep an attentive watch upon these novelties, and, whenever the circumstances warrant, give them a fair trial by applying the test of clinical experience.

Orexin appears to be one of the substances which deserve such a trial. Merck and his friends introduced it as the ideal appetizer; a drug which has the specific property of increasing the appetite, regardless of the pathological condition underlying the anorexia. There is room for such a remedial agent, though it would doubtless be greatly abused. In the chronic pulmonary diseases, the lack of appetite is one of the greatest obstacles to treatment; especially as it is acknowledged that our best therapeutic measure is increasing the nutrition. So much is this so that Cohen considers forced feeding essential. On the other hand, another observer, after an apparently impartial trial, finds the drug of so little value that the *Therapeutic Gazette* concludes we need not consider it further. There are some, however, who knowing the very high estimate Dr. Wood sets upon his own investigations, and the very low one upon those of the rest of the world, do not care to accept this dictum as final.

Ranking ourselves among these, we sent to Merck's New York house and procured a bottle of fifty tablets, each containing one and one-half grains of orexin, which were given with the following results:

The first case was one of anorexia from chronic alcoholism, heat, and ice-water. The woman has some cirrhosis, no ascites, but pain in the left hypochondrium. She was directed to take one tablet every morning at 10.30, followed by a cup of hot water. Nothing was said about the expected effect, or the reasons for giving the medicine. Three days later, when asked what results followed, she attempted to describe some vague sensations, evidently quite at a loss as to what was expected. After some further conversation the question of appetite was brought in casually, when she remarked that there was no trouble about her appetite, as she ate five meals a day, and was even then not satisfied.

The next case was that of a teacher, anemic, nauseated, and enfeebled by long exposure to air contaminated by sewer gas. She reported slight improvement in appetite for some days, when an attack of diarrhœa supervened, for which she blamed the orexin, but which was probably due to the heat and unwholesome food. If the orexin did any good in this case, it was very little; in fact, there was no benefit beyond what could be attributed to rest and quiet.

The third case was a curious one of chlorosis, with gradual darkening of the skin, which has been progressing for eight or ten years, with no other cause assignable than a questionable malarial infection. She took one tablet daily for a week, with no perceptible benefit.

The fourth case was that of a gentleman, sixty-eight years of age; plethoric; a steady whisky drinker; with chronic cystitis and its gastric concomitants. He took the tablets under the impression that they were intended to cause sleep. After three days he reported his appetite as "fairly good; about as usual." This, with him, meant that it was as good as when at his best.

Up to this time the orexin had been given only in the very small dose of one and one-half grains. Had the experiment stopped here the impression would have been rather unfavorable, as but one case was manifestly benefited, and three not materially improved. The dose was then increased to two and three tablets, containing three and four-and-one-half grains. In the case of the old gentleman, the enlarged dose produced somewhat more appetite. Although much adverse to medicine, preferring to consider whisky a panacea, he requested a continuation of the tablets—an unprecedented incident in his history.

In the second case there was a little more evidence of benefit when three grains were given.

The third case reported some improvement; but as she now knew what the tablets were given for, her testimony is not wholly reliable.

Finally, the orexin was given to another lady—a case of pulmonary fibrosis, of long duration, who has been confined to her bed for over a year. She is very sensitive to the action of drugs, and not at all imaginative as to their beneficial effects. She took two tablets for three days, and reported that during that period her appetite was ravenous, but her head ached constantly and severely.

These were not selected cases, but simply those which came under observation at the time in which the anorexia was marked and its relief a leading indication. But fifty tablets were used in all. The experiments are, of course, too few to settle the question as to the value of orexin; but they are sufficient

to indicate that the assumption of its uselessness on the testimony of a single witness is not to be accepted as final. The doses given in Germany were possibly too large; or the cases may have been those in which the anorexia depended upon a cause which should have demanded first treatment. At any rate, we should have the testimony of a number, using the drug in varied doses and modes of administration, before we "drop its further consideration."

—W. F. WAUGH.

Annotations.

IF all cities were as wise as Egg Harbor, there would be a demand for doctors to fill the office of mayor For fifteen years the black rot has devastated the vineyards of Egg Harbor, and all efforts at remedying the disease have failed. This summer, however, the mayor, Dr. T. H. Boysen, has succeeded in saving his vines, which are now loaded with fruit. He employed the "Bordeaux mixture," which had previously been used without success. Believing that the failure was due to the faulty method of application, Dr. Boysen concluded to give the remedy a more thorough trial. He employed an atomizer, and sprayed the mixture over the vines before they sprouted. This was repeated just after blossoming, and three times since. The cost is slight. Hundreds of grape-growers have visited Dr. Boysen's vineyards, to witness the results of his method.

DR. ALICE BENNETT has found it necessary to complain to the trustees of the Norristown Hospital, of the poor quality of the flour supplied to that institution. This is hardly in accordance with the views upon hospital management held by the authorities of that institution, who advocate the restriction of the physicians to purely medical treatment. We have always claimed that such a limitation is inconsistent with the best interests of the patients, and Dr. Bennett's action fairly demonstrates the correctness of our position. If the bread is bad, it is the physician's duty to call attention to it; and she should have the power of enforcing a prompt change for the better. Now, it must go to the trustees, who order an investigation, and perhaps some time the matter will be remedied, if the trustees do not forget it.

THERE is a general impression that the people of Australia are a pretty active race, judging by the performances of their oarsmen and cricketers. But the virtue of fastness is not to be credited to the entire community, judging from the hospital intelligence of the last *Australian Medical Journal*. An offer of five thousand dollars was made by a friend, for the purpose of building an operating theatre; but so long a time elapsed before the authorities concluded to accept the gift, that the donor withdrew his offer.

Eighteen of the night nurses complained of their superior, who was notified of the illness of a nurse, but did nothing to relieve her. She was compelled to go on duty while still distressed with pain, and died.

VOMITING of pregnancy must be a remarkable disease, judging from the numerous remedies which have been advocated for it; none of which will relieve it. In the *Australian Medical Journal*, Carney mentions a case, for which he applied a saturated solution of cocaine to the whole of the vaginal wall, the cervix, and the cervical canal, and a suppository containing a grain of cocaine and a quarter-grain of morphine was placed against the os uteri. The patient did not vomit for eight hours; when another application was made, and recovery ensued.

The large quantity of cocaine employed in this case is not safe, as alarming symptoms have followed when much less was used. Such a thorough application of an antiseptic, such as iodine, permanganate, or creolin, would, we believe, produce quite as satisfactory a result. The theory which attributes vomiting of pregnancy to the absorption of ptomaines from the cervico-vaginal canal is one which is deserving of a full trial in practice.

THE first execution by electricity has at last been accomplished. Judging from the reports of eye-witnesses, it was not wholly successful, as a second application was required before motion ceased. There seems to be no reasonable doubt that consciousness was extinguished by the first shock, and that death was wholly painless.

The comment of Mr. Edison seems quite apposite, that it was a mistake to put the arrangements into the hands of physicians, who had no experience in electrocution. The electric light companies could have accomplished the object with neatness and despatch.

Even as it is, this method is preferable to hanging; and, with a little more experience, electricity will yet be found the best agent for execution; destroying the fated victim with the sudden and painless lightning stroke.

Letters to the Editor.

RESTORATION OF THE NOSE AFTER IT HAD BEEN ENTIRELY DETACHED FOR AN HOUR.

ON July 1, I was called to the Kincaid Cotton Mills, Griffin, Ga., and, upon my arrival, I found a young man bleeding from the nasal locality. After examination, I discovered that all the soft part of his nose was gone, except about one-third of the left wing and a thin anterior flap of the nasal septum, which was lying down upon the upper lip, still attached at its lower end. I was informed that it was cut off by a belt which had slipped off of its pulley while the machinery was in motion.

I ordered the missing member brought to me; after a short search it was found. I washed it and warmed it thoroughly in warm water lightly impregnated with bichloride of mercury; placed it in its proper position; raised the anterior flap, and stitched all around with surgeon's silk. I then introduced into each nostril two large drainage tubes, compressed and confined the parts firmly with several strips of isinglass plaster.

Over the entire nose I placed a piece of oiled silk. During the first twelve hours I kept up continual warmth by laying across the nose a flannel doubled three or four times, saturated with a warm solution of bichloride mercury. I also injected frequently this warm solution into the nostrils.

On the second day nothing was done except to keep a dry flannel across the nose. On the third day I removed the drainage-tubes, washed out each nostril with warm bichloride solution, dried the parts, and

placed the tubes back as before. I repeated this almost daily until the tenth day, when I removed all of the dressing and found the nose alive and united except a small triangular notch in the right wing, which was so badly bruised as to cause it to die. The time the nose remained off was about one hour, which fact renders this case a very important one to the medical profession. I attribute my success to absolute cleanliness and uniform warmth during the first few hours.

In a few days I will restore the slight deformity by paring and bringing the edges together.

GRIFFIN, GA.

Book Reviews.

RAILWAY SURGERY. A practical work on the Special Department of Railway Surgery; for railway surgeons and practitioners in the general practice of surgery. By C. B. STEMEN, A.M., M.D., LL.D. With numerous illustrations; 1890, J. H. Chambers & Co., publishers, St. Louis, Mo.

This book is the outcome of the author's belief that railway surgery has grown so important that it deserves special practitioners, special journals and special text-books. It is claimed that over 25,000 American surgeons are engaged in this special work; while but little reference is made to it in the college course or in ordinary works on surgery. The correctness of these assumptions each of our readers must decide for himself. If he needs a special work on railway surgery, he will find Dr. Stemen's book of much practical value. He treats of the transportation of injured men, temporary treatment, shock, anesthetics, lacerated wounds, fractures, amputations, hemorrhage, excisions, cerebral concussion and compression, burns, color blindness, injuries to the hand and feet, spinal concussion, transfusion, aneurism and the care of the sick or injured on foreign railroads.

In spite of the author's claims, there is little which is not to be found in the systematic works on surgery. The illustrations are mostly old friends, from the instrument makers; while of the four that illustrate the results of operation, that on page 156 is remarkable in that it presents a view of the sound shoulder, while the one that was operated upon is turned away so that only a glimpse of the margin of the wound is given. The prescriptions are dreadful; a mixture of Latin and English, nominatives and genitives, some adjectives capitalized and others not, punctuated or not, spelling variable. Glycerine, on page 29, becomes glycerin on page 93. Putrifaction, locunated, perafine and vasaline, ought not to have escaped the eye of the proof-reader.

The material taken from Dr. Stemen's practice and that of his colleagues in the National Association of Railway Surgeons, forms the most valuable part of the book, and might with advantage have been largely increased. The subject of railway surgery is capable of much better handling, and as this is the pioneer work on the specialty, we may expect to see a great improvement in Dr. Stemen's subsequent editions.

The bookmaker's part, typography, paper and binding, is so well done as to merit special mention.

Pamphlets.

What is the Present Medico-Legal Status of the Abdominal Surgeon? By William Warren Potter, M.D., Buffalo, N. Y. Reprinted from the *American Journal of Obstetrics and Diseases of Women and Children.*

Twelfth Annual Report of the State Board of Health of the State of Rhode Island, for 1889. Including the report upon the registration of Births, Marriages and Deaths in 1888. Providence: E. L. Freeman & Son, State Printers, 1890.

The Pennsylvania Museum and School of Industrial Art. Circular of the Committee on Instruction, 1890–91. Classrooms: 1336 Spring Garden Street, Philadelphia, 1890.

Cholecystotomy. By Edward Ricketts, M.D., of Cincinnati, O. From *The Pittsburgh Medical Review*, May, 1890.

External Surgery of the Nose. By B. Merrill Ricketts, Ph.B., M.D. Reprinted from *The Journal of the American Medical Association*, June 21, 1890.

Five Cases of Vaginal Hystorectomy for Malignant Disease of the Uterus, all Recovered. By W. F. McNutt, M.D., L.R.C.P., Ed., etc. Reprinted from Transactions of the Medical Society, State of California, 1890.

The Use and Abuse of Soap and Water. By B. Merrill Ricketts, M.D. Reprinted from the *Journal of Cutaneous and Genito-Urinary Diseases.*

A New Operation for Prolapsus of the Anterior Vaginal Wall. By Andrew F. Currier, M.D., New York. Reprinted from *Annals of Gynæcology and Pædiatry.*

The Medical Digest.

PYOCTANIN has been used by Kanne (*Weekly Med. Review*) in a case of acute gonorrhœa, which was cured in three days by three injections of a 1 to 1,000 solution.

THOMPSON, in the *Journal of the National Association of Railway Surgeons*, attributes acquired color-blindness to the abuse of alcohol and tobacco. He says that the scotoma in tobacco and alcohol amblyopia often includes the fovea centralis, which makes the color-blindness central and extremely dangerous.

DIPHTHERIA OF THE MEATUS URINARIUS.—A case is reported by Brown, in the *Journal of Cutaneous and Genito Urinary Diseases.* The source of inoculation was probably a piece of cotton, placed upon the meatus after circumcision. In thirty-six hours a considerable wax-like mass developed, consisting wholly of bacteria. No disease appeared in the circumcision wound. Albuminuria was found present, and subsided with the convalescence.

CASCARA SAGRADA.—In the *Atlanta Med. and Surg. Journal*, Murphey gives the following formulas for using cascara, as a laxative:

℞.—Ext. cascaræ sag. fl..... ℥j.
Glycerini..... ℥ss.
Syr. tolutanæ..... ℥ss.
Aquæ..... q.s. ad ℥iv.
M.—S. Teaspoonful twice daily, before meals, soon reduced.

℞.—Ext. cascaræ sag. fl..... ℥ss.
Tinct. nucis vom..... ℥iij.
Tinct. rhus tox..... gtt. xv.
Syr. tolutanæ..... ℥j.
Aquæ..... q.s. ad ℥iv.
M.—S. ℥j. in water before meals, for constipation and indigestion.

TETANUS WITH RECOVERY.—Tetanus is a disease sufficiently formidable to make the therapeutics of a successful case one of interest to the profession. A glance at the books shows, by the long list of remedies recommended, how uncertain all of them are in a given case.

V., aged thirty, had his wrist torn and lacerated by a large jagged sliver; wound healed nicely. By the fourth day there was pain and stiffness in both arms, which gradually extended to the body generally.

As soon as the nature of the case was recognized he was put upon chloral gr. xv, with potas. brom. gr. xxx, every two hours. After a week gr. $\frac{1}{8}$ of morphine was added to each dose, with undoubted benefit. This treatment was continued for a month before its abatement would not be followed by aggravation of symptoms. Recovery was slow, but satisfactory. No attention was paid to an abundant eruption due to the bromide.—Pratt, *Pacific Med. Journal.*

Albuminuria of Pregnancy.—Griggs (*Southern Med. Record*) recommends the internal administration of chloroform for these cases. The symptoms that indicate the need of testing the urine are: The swollen sensation of the hands and face; the rings tight; general puffiness; pain over the crown of the head; perverted vision; altered speech; diminution of urine. If there are six to eight weeks before the expected parturition, he begins with twelve drops of chloroform, increasing to twenty. If nearer the term, the dose should be larger. The doses are to be taken before meals, thrice daily, and at midnight; in an ounce of water. If the albumin increases, the dose must be larger. The drug is to be continued as long as the albumin does.

Gleet.—Allen (*Boston Med. and Surg. Journal*) thinks the best method of treating gleet is by making local applications to the diseased surface through the endoscope. He prefers nitrate of silver, beginning with a 1 per cent. solution and gradually increasing to 10 per cent., applied every four to seven days. In the interval, ordinary astringent injections may be used, or corrosive sublimate irrigation, 1 to 1,000 or 2,000, the sound passed, etc., if thought advisable.

Stricture with glandular disease is tedious, but generally ends well.

Simple inflammations require about a dozen sittings.

In treating the posterior urethra, Keyes' method of deep injections is advocated. Good results are obtained from irrigating the neck of the bladder with permanganate solutions. This has none of the risks of silver. Some of the solution should be left in the bladder. For this operation, Ultzmann's syringe-catheter is useful.

Prescriptions from the Nervous Department of the Vanderbilt Clinic:

Brown Séquard Mixture:

℞.—Potass. iodid..... gr. vj.
Potass. bromid.,
Ammon. bromid .... āā gr. xv.
Sodii bicard..... gr. iv.
Tinct. nucis vomicæ..... ♏vj.

FRENCH NOTES.

By A. E. Roussel, M.D.

Treatment of Rachitis (Kassowitz).—

1. (For poor patients):

℞.—Phosphorus..... 0 gr. .04
Cod-liver oil..... 100 grammes
Make emulsion.
One teaspoonful a day (= 0 gr. .0005 of phosphorus).

2. (For rich patients:

℞.—Phosphorus..... 0 gr. .01
Lipanine..... ..... 30 grammes.
Sugar,
Powdered gum arabic.....āā 15 "
Make emulsion.
One teaspoonful in the twenty-four hours.

3.

℞.—Solution of phosphorus in oil of almonds (00–0.2) ..... 5 parts.
Cod-liver oil..... 95 "
Make emulsion.
One teaspoonful a day.

This treatment should be continued for a prolonged time without interruption.—*Le Bulletin Médical.*

Chromic Acid for Sweating of the Feet.—By order of the Minister of War of Prussia, experiments have been made since 1889 with pure chromic acid to relieve sweating of the feet, experiments which have resulted satisfactorily. Often it was only necessary to bandage a single time the entire foot with cotton soaked with a five per cent. solution, so that it was rarely necessary to repeat the treatment or use a stronger solution. The parts treated with the solution of chromic acid become dry and hard, which increases the tendency for long marches in a very considerable manner. If there are any wounds on the feet, it is better not to commence the chromic acid treatment until they are cured. Finally, no secondary affections have been noticed, nor complications due to the suppression of the sweats by the chromic acid.—*Journal des Maladies Cutanées, etc.*

TREATMENT OF HYPERTROPHY OF THE PROSTATE. (Kobner).—

℞.—Iodide of potassium..... 3 grammes.
Bromide of potassium .....2.5 to 3 "
Extract of belladonna..... 30 centigr.
Water..... 200 grammes.

For twenty enemas.

M.—Inject each time 20 grammes of this solution in 50 to 100 grammes of hot water; once a day at first, later twice daily.

Later on we increase the dose, and we prescribe:

℞.—Iodide of potassium ..... 10 grammes.
Bromide of potassium..... 8 "
Extract of belladonna .... 0.60 centigr.
Water..... 300 grammes.

25 grammes of this solution in 80 to 100 grammes of water twice a day.

Kobner found that in adding to each enema five to ten drops of pure tincture of iodine, the mixture was very efficacious, and was tolerated by the large intestine.—*Revue de Therapeutique.*

CHLORIDE OF SODIUM IN FACIAL NEURALGIA.—In doses of one teaspoonful to one tablespoonful chloride of sodium is said to possess the property of cutting short an attack of migrane or other nervous manifestations.

According to Dr. Leslie the same substance will cure facial neuralgia, odontalgia, earache, nervous headache, not by internal use, but as an application to the nasal mucous membrane; taken as snuff, or by means of an insufflator, in the nostril of the painful side.—*Revue Médicale.*

TRANSMISSIBILITY OF TUBERCULOSIS BY MUSICAL INSTRUMENTS.—Dr. Maljean has observed a case of tuberculosis in a musican, which he concluded was due to the use of a trumpet which previously belonged to a phthisical patient. To demonstrate the fact he introduced through the tubes a certain quantity of sterilized water, which he agitated for ten minutes. Two centimeters of the liquid was subsequently injected in a guinea pig. The animal died of tuberculosis.—*Bulletin de Thérapeutique.*

NOTES UPON SOMNAL, THE NEW HYPNOTIC. Frank Woodbury, A.M., M.D. *Dietetic Gazette*, July.—Last fall Radlauer,[1] of Berlin, brought to the notice of the medical profession a new compound to which he gave the name of Somnal, in acknowledgment of the remarkable hypnotic properties which it appeared to possess. It was formed by the union of chloral, alcohol, and urethan, according to the original notice,[2] but is not a simple mixture of these bodies. It differs from chloral-urethan by the addition of $C_2 H_4$, its formula being $C_7 H_{12} Cl_3 O_3 N$. The method of manufacture is by direct combination of chloral alcoholate and urethan in a vacuum apparatus, according to its discoverer, who states[3] that its composition might be graphically represented thus:

$$C\,Cl_3—C(OC_2H_5)(H)—NHCOOC_2H_5$$

Specimens of this new hypnotic having, through the courtesy of Messrs. Eisner and Mendelson Co., been placed in my hands for examination and trial, I will here very briefly communicate some of the results thus far obtained, reserving my final judgment upon the drug until experience has been more extended.

[1] Zeitschrift des Apothekers Vereins, Nov., 1889.
[2] Journal de Médecine, Oct. 20, 1889.
[3] Pharmaceutical Journal and Transactions, Nov., 1889.

Physical Characters.—Somnal is a colorless liquid, resembling chloroform in its appearance and behavior when added to cold water, in which it forms globules and refuses to mix or dissolve. When shaken with water the mixture is milky, but quickly separates. It is soluble in hot water and alcoholic solutions, and dissolves resinous substances and fats. The odor is faint, not very penetrating or disagreeable, and resembles that of the spirits of nitrous ether, or recrystallized chloral The taste is very pungent; and for administration it needs free dilution. It may be given with whisky, or solution of tincture of zingiber, or syrup of licorice. Somnal is inflammable, burning with an alcoholic flame; it does not evaporate quickly, and leaves a greasy stain upon blotting paper. Specific gravity greater than water; reddens litmus paper slightly.

Physiological Effects.—In its action it resembles chloral in quickness of effect and naturalness of the sleep produced. No marked depressing influence was exerted upon the pulse or respiration rate, though it was noticed that the breathing became slower and the pulse slower and fuller, as in natural repose. No disagreeable after-effects. The head was clear and the stomach was unaffected; the patients generally had an appetite for breakfast. No constipating effect. The kidneys acted rather more freely than usual. My colleague, Dr. Ernest Laplace, to whom I gave some of the drug for trial at the Philadelphia Hospital, writes as follows:

"I have given somnal a fair trial upon six patients at the Philadelphia Hospital. In no case were the patients told what was given them, so that outside of the bare possibility of the patients' falling asleep through natural causes, somnolence was brought on by the drug. It was administered in a solution of tinct. zingiberis, in half teaspoonful doses, and was found palatable.

"Administered at 4 P. M., at a moment when patients were not generally asleep. In four cases sleep came on within half an hour, which lasted from five to eight hours; the two other cases showed no effect from the drug. It is their habit to get at least gr. ¼ of morphine sulph. to put them asleep every night, as they are suffering from intractable malignant growth.

"In no case was there any noticeable after-effect.

"I have not formed any opinion upon the length of time that the drug could be used daily upon the same patient.

"To this I might add that no depression of the normal temperature was noticed in any case in my hands, and thus far I have not used it in pyrexia."

Therapeutic Application.—The effects of somnal in producing natural sleep suggest its use in insomnia. The first case in which I used it was in a patient suffering with acute alcoholism, who had been under treatment for a fortnight in an institution, where he had a free supply of liquor, and he came out rather worse than he went in. He was thirty-nine years of age, very tremulous, and could not sleep; or, if he dozed off, would immediately waken up. I gave him, at about 3 P. M., thirty minims of somnal (or rather a drachm of a mixture of equal parts of somnal and whisky), well diluted, and went into an adjoining room to speak to an attendant. Upon my return I was surprised to find him fast asleep, although I had not been away from him more than fifteen minutes. He slept for four hours, and then was able to take something to eat. At 10 o'clock he had another dose, and he slept until 7 next morning, having wakened up once only during the night, and insisted

upon having another dose, and immediately after taking it he fell asleep again. The next night he was given a double dose at 10 o'clock, and he slept all night without wakening. No bad effects were observed. The somnal was given for four nights, when he was so nearly well that it was suspended, as he had had good natural sleep at night, and seemed quite restored. Alcohol was positively prohibited, the only substitute allowed being Elixir of Coca and Camellia (P. D. & Co.), in tablespoonful doses, in which, it is true, there was a small amount of alcohol, which was quite infinitesimal when compared with what he had been using. Somnal, therefore, acts well as a hypnotic in acute alcoholism as a tranquilizer and hypnotic.

In a case of neuralgia of the bowels (visceral neurosis of Allbutt), where the patient had a sleepless night, a dose of twenty minims relieved nausea and pain, and the patient fell asleep.

In syphilitic headache and insomnia, somnal, in moderate doses, failed to produce sleep, which was afterward secured by potass., bromide and iodide, and antipyrine.

In cases of insomnia, fretfulness, and restlessness in young children, somnal with mint-water and syrup offers better results than opiates, and is much safer. The same remark probably applies to the use of somnal in acute pneumonia, but I have not been able to confirm this yet by actual trial.

Without further going into detail, it may be stated in conclusion that somnal acts as a hypnotic, but instead of depressing the system as chloral does, it slightly stimulates the gastric mucous membrane, relieves nausea and pain, improves the appetite, increases secretion (probably), does not cause constipation. The circulation, respiration, and temperature are not notably depressed after its administration. No disagreeable after-effects have been observed. As it is rapidly eliminated from the body, it may be administered each night for a number of days without any obvious ill-effects. It acts very much like chloral, but is more pleasant to take, and not so depressing in its effects upon the nervous system and the circulation.

The Mortality of Widowers from Phthisis.—In a paper, on Tuberculosis in Belgium, MM. Destrée and Gallmaerts come to the conclusion as the result of their investigations that, in comparing the mortality from phthisis of bachelors, married men, and widowers, the last are very much more subject to this disease than either of the other classes. The same statement holds good for all ages, and it is, they say, also true that widows are more liable than single women to die of phthisis. The authors do not think this is to be explained except by direct contagion of wife to husband, or husband to wife. They cannot think irregularities and excesses indulged in by widowers can be answerable for it, for advanced age does not seem to make any difference. They would ascribe it to infection occurring during married life, the disease claiming its second victim some time after the death of the first.—*Lancet.*

Ice in Strangulated Hernia.—A case which, I think, well illustrates the occasional value of ice in strangulated hernia occurred recently in the West Bromwich District Hospital.

T. F——, a laborer, aged thirty-five, came to the hospital on July 15, at 8.30 P.M., and was admitted under the care of Mr. Langley Browne. The history he gave was that while at work that morning, at about 10.30 A.M., he had a sharp pain in the groin, and "felt something slip." He then found that there was a lump in the right groin, and went home and remained in bed. He was sick about five times during the day, and was seen by a medical man in the evening, who ordered him to go at once to the hospital. On admission there was found a rounded swelling, the size of a tangerine orange, occupying the right groin, immediately over the situation of the external abdominal ring, which was tender on pressure, quite devoid of impulse, and irreducible. He immediately vomited on taking anything by the mouth, and had passed no flatus since the accident occurred. The patient was at once placed in a warm bath, and reduction attempted while he was in the bath. This failing, he was put to bed, and the parts were shaved ready for an operation. However, as the symptoms were not very urgent, he was given one grain of opium, and an icebag was applied to the groin. He vomited four times during the night. At 10.30 A.M. on the following morning the taxis was again tried, with the result that the hernia was easily reduced.

—Wilkinson, in *The Lancet.*

Induction of Premature Labor. — In these days, when abdominal section is so freely practiced, obstetricians of authority tend to throw discredit upon the induction of premature labor and craniotomy, and so advocate Cæsarean section. Prof. Ahlfeld, however, has lately issued an important monograph of 118 cases of induction of labor, performed by himself and his assistants between 1871 and 1890, at Leipzig, Giessen, and Marburg. In 111 of these cases labor was induced on account of deformed pelvis; in the remaining 7 it was undertaken because of some general illness. Only one mother appears to have died from the direct results of the proceeding in question; she succumbed to damage of the soft parts caused by the passage of a large head through an atypical pelvis. Four mothers died from diseases which either followed accidentally or were those for which labor had been induced—convulsions, tuberculosis, heart disease; 75 mothers recovered without rise of temperature. One hundred and twenty-one children were thus delivered (there being three cases of twins in the 118 labors). Of these 19 were stillborn, 18 died in the course of the first day, 9 died before the mother was discharged, and 75 left the hospital, etc., alive. Out of 99 carefully registered contracted pelvis cases (including two twin labors) 86 children were born alive, 15 stillborn, and 61 survived. On the other hand, in 6 cases of Cæsarean section performed in Prof. Ahlfeld's wards, 2 mothers and 1 child died. Space forbids any notice of the author's statistics as to the extent of contraction in the pelves. The monograph deserves close study. Prof. Ahlfeld insists that the introduction of a flexible bougie into the uterus without rupture of the membranes is by far the best method, but the pains are apt to be slow, so that accessory means are sometimes required. There can be no doubt that the majority of practical obstetricians are more likely to attain good results by inducing labor than by performing Cæsarean section or Porro's operation.

—*British Medical Journal.*

Disinfection by Sulphur.—The following letter has been forwarded to us. The importance of the subject fully warrants us in publishing it in full:

SAMUEL P. DUFFIELD, M.D.,
Health Officer of the City, Detroit, Mich.

DEAR DOCTOR:—In the Detroit newspapers to-day, in a synopsis of your annual report, I see that you propose to displace disinfection by fumes of burning sulphur. Permit me to ask your attention, and that of the Detroit Board of Health, to some facts which bear on this subject, and which could not be had except through this office:

Excluding Detroit and Grand Rapids (the data from which cannot be profitably included with the data from the smaller places), the official reports to this office prove, beyond a reasonable doubt, that isolation and disinfection do restrict diphtheria. I send herewith three diagrams, in which are condensed the experiences of health officers throughout Michigan in over a thousand outbreaks of diphtheria in the years 1886, '87, and '88. They prove that, in those outbreaks in which isolation and disinfection were *neglected*, there were, on the average, over fourteen cases, with nearly three deaths to an outbreak. They prove that, in those ourbreaks in which isolation and disinfection were *enforced*, there was an average of only a little over two cases, with only about one-sixteenth of one death to each outbreak; and it must be remembered that these figures relate to instances in which at least one case of diphtheria had already occurred in the community, and that occasionally several cases occur at once, on the start.

The method of disinfection referred to is that recommended by this State Board, namely: burning three pounds of sulphur for every thousand cubic feet of air space in a room, infected articles being loosely spread out; and, because of movements of infected articles from the sick room, and from one room to another, all rooms in the house are disinfected, together with all the contents.

The evidence of the complete success of this method throughout the State (except in Detroit, and possibly Grand Rapids) is so conclusive that it seems to me certain that any failure in Detroit must be due to some imperfection in the application of the method of disinfection. I do not claim that Dr. Chapoton's suggestion is correct: that it "was attributable to the carelessness of the disinfecting physician." I think it is quite likely that the failure in Detroit is due to the use of *too little sulphur;* possibly, also, to the use of something else with the sulphur. (Possibly the exact weight of the sulphur may not be correctly estimated when mixed with another substance).

I respectfully submit that a *few* laboratory experiments should not be allowed to prevail against two hundred and fifty successful ones in the experience of health officers in restricting actual outbreaks of diphtheria in Michigan. During the last three years the known saving of life in Michigan from diphtheria, by isolation and disinfection, has averaged one and a half persons per day.

However, there are many laboratory experiments which coincide with the experience of health officers in Michigan. I send you herewith a hektograph copy of an account of experiments by Pasteur and M. Roux, with the co operation of Dujardin Beaumetz, which prove both the points which I desire to make: (1) that the burning of two pounds of sulphur per one thousand cubic feet of air space is *not* always certainly effective, and (2) that three pounds *is* effective. This applies to a closed room; if there are openings through which the fumes may pass more sulphur is required.

Permit me to suggest that if any method of disinfection is adopted, which involves the movement of infected clothing or other articles through the streets to a central disinfecting station, that no such removal be permitted until after such articles have been submitted to disinfection by fumes of burning sulphur, or by chlorine gas, or other equally effective gaseous disinfectant, which shall thoroughly permeate the room and contents.

From my practical experience and observation with such disinfectants, I wish to commend the method by fumes of burning sulphur, *without* the addition of extra moisture to the atmosphere. When such moisture is added many valuable articles are destroyed, which, without such moisture, would not be injuerd.

I trust that this entire subject will receive thorough investigation by your Board, and I shall be glad to be informed of the result. The State Board of Health desires to utilize, for the entire State, all new methods and all new facts which you can supply on this important subject. Very respectfully,

HENRY B. BAKER, *Secretary.*

DISINFECTION BY FUMES OF BURNING SULPHUR.—Experiments by Pasteur and M. Roux, in the Cochin Hospital, of Paris, were carried on under the observation and with the co-operation of Dujardin-Beaumetz, physician to the hospital, and one of the most eminent medical authorities of France. Dujardin-Beaumetz makes a summary report of the experiments, in a work entitled *Les Nouvelles Medications.*[1] A few paragraphs, from pages 76 and 77 of this work, show substantiallv as follows:

"Twenty grammes of sulphur to a cubic meter (1.53 per 1,000 cubic feet of air space) destroys the different micro organisms in a moist state, but it is necessary to increase this dose if one wishes to destroy some organisms in a dry state. In fact, since the last communication to the Academy, M. Bardet and myself, aided by M. Chambou, have continued these experiments upon micro-organisms in a dry state, and particularly upon vaccine virus. We have taken from the pustules of vaccinia, scabs which we have reduced to fine powder, and placed in chambers where were variable quantities of flowers of sulphur. When a dose did not exceed 20 grammes per cubic meter, the vaccine powder did not lose its properties, and one could, by inoculating animals and infants, obtain a vaccine eruption.

"With 30 grammes per cubic meter, (2.297 pounds per 1,000 cubic feet of air space) the results obtained were uncertain, sometimes the powder loses its properties; but when the dose is increased to 40 grammes per cubic meter, (3.06 pounds per 1,000 cubic feet of air-space) the inoculations are always inactive. So then, for vaccine, and probably for variola, if one desires to destroy the contagious "germs" in a dry state, it is necessary to double the dose of 20 grammes, which we have already fixed.

"According to the experiments of Vallin, and of Legouest, 20 grammes are sufficient for typhoid fever, while, according to Vallin, 40 grammes are necessary for the microbe of tuberculosis.

"(In the case of beef tea cultures, the dose must vary according to the micro-organisms experimented with.)

"The results at which we have arrived are absolutely confirmative with those which have been previously obtained by Polli, of Milan; Pettenkofer, of Munich; Dougall, of Glasgow; Fatio, of Geneva; and Pietra Santa, of Paris, and finally of the researches of Vallin, published in his able work upon disinfectants."

[1] Translation for this note has been received from John H. Kellogg, M.D., Battle Creek, Mich.

Medical News and Miscellany.

DENGUE is prevalent in Senegal.

SATURDAY half holidays make the lives of workers easier all the week.

BIDDEFORD, Maine, prosecuted a milkman for selling milk on Sunday.

THREE Manayunk families were poisoned last week by eating fish bought from a huckster.

THE Chinese pay their doctors as long as they remain well; as soon as they get sick their pay stops.

THE Medical Examining Board of Virginia will meet at Rockbridge Alum Springs, Sept. 2, at 8 P.M.

A NEW YORK physician recommends the introduction of the telephone into the infectious disease hospitals.

ELECTRICITY is used for taming refractory prisoners in the Ohio penitentiary, instead of the hose and cold water.

A CHICAGO college student was recently committed to the insane asylum, adjudged insane from cigarette smoking.

THE Antwerp Provincial Council divided its subsidy for treating hydrophobia between Pasteur and St. Hubert!

ALTERATIONS have been begun in the Clinic Ward of the University Hospital, which will add more room to that department.

THE census-taking in New York has developed the fact that more than sixty languages and dialects are spoken in that city.

DRS. W. M. L. COPLIN AND R. P. ROBINS have been elected out-door physicians by the Board of Charities and Correction.

A FAITH-CURE doctress at Omaha treated a woman in confinement recently; the mother and child both died. The curest is under arrest.

SALIPYRIN is a salicylate of antipyrin, patented, but not yet sufficiently through the experimental stage to be given to the profession.

DR. W. F. WESTMORELAND has been elected to the Chair of Surgery in the Atlanta Medical College, left vacant by the death of his father.

DR. HAL. FOSTER, of Kansas City, Mo., has recently received the appointment of Laryngologist to the Missouri Pacific Hospital at that place.

IT is said that local anesthesia can be produced by discharging two or three syphons of aërated water on the part. The anesthesia lasts five minutes.

PHILADELPHIA prohibits the use of the phonograph for fear of infection from the ear pieces; but the public drinking cup still remains at the Park fountains.

EDSON says that thorough sulphur fumigation is effective against small-pox contagion, less so against scarlatina, and untrustworthy against diphtheria.

THE epidemic at Preston, Iowa, proves to be a malignant type of dysentery. Eighteen deaths have occurred in as many days, but the epidemic is said to be abating.

ENGLISH JOKE.—When a woman has twins, one black and the other white, it is evident that the fact of superfœtation has been proved in black and white. Now, all laugh.

MICHIGAN bears up under the infliction of typho-malaria, puerperal fever, enteritis, cholera infantum, and diphtheria, all of which were reported on the increase on July 19th.

THE Norristown Board of Health held a meeting last week to consider Dr. Cresson's report of impurities found in the Schuylkill, which befouled Norristown's water supply.

DR. WILLIAM RUPP, of Myersdale, read a paper upon "The Influence of the Christological Principle," before the Spiritual Conference of Reformed Church clergymen, at Lancaster.

IN April Melbourn reported 1,478 births and 973 deaths, giving to each 1,000 of the population a ratio of 3.22 births and 2.12 deaths; or an annual rate of 38.64 births and 25.44 deaths.

IN Melbourne, Australia, during the first four months of 1890, there were 303 deaths from typhoid fever, and 177 from diphtheria; not including, in the latter, 20 deaths from diphtheritic croup.

PROF. HUXLEY has written to the New York *Times* on Medical Education. He wrote apropos of the meeting of the British Medical Association at Birmingham, and of its President's address.

THE University of Lewisburg has conferred the degree of Master of Arts on Dr. Joseph R. Clausen, a physician of this city. Dr. Clausen is the Sitting Past Supreme President of the Order of Tonti.

A KANSAS editor has recently been granted a pension of seventy-two dollars a month for indigestion. He will soon recover from his indigestion now that he has the means of buying something to digest.

MARION county, Illinois, has gained the credit of having the stingiest man on earth. He tried to buy part of a bottle of patent medicine for his son, who, he claimed, would die before he could consume the entire bottle.

CORONER ASHBRIDGE held an inquest last week upon the body of Edward J. Steward, colored, who died in the insane department of the Philadelphia Hospital, from scalds accidentally received while bathing.

JOINT committees of the Southern and Northern Dental Associations, at Excelsior Springs, Missouri, last week, decided to begin arrangements at once for an International Dental Congress at Chicago during the World's Fair.

IT seems that there is danger in cleanliness in New York. It is reported that children are getting ophthalmia at the Market street public bath, it is believed from using towels which others, affected with the disease, have made use of.

DR. E. N. BUSH stated, in a paper read before the Association of Superintendents, that during eight years' trial of women physicians of insane asylums, there were fewer cures and more deaths in the asylums where the female physicians were employed.

MRS. SCHMIDT, her daughter, and four boarders, of Pittsburg, were made seriously ill on Saturday by drinking coffee in which poison had been placed. A Mrs. Levi, a business rival, who was seen crawling from a window of the Schmidt's house on Friday evening, has been arrested.

UGLINESS as a disqualifying cause seems intelligent in a candidate for matrimony, but is certainly less so when the question is one of fitness for military service. This, however, is one on the list of disqualifications laid down by the head of the Medical Department in a manual just issued on "Conscription in France."

THE Medical Academy for Women in St. Petersburg is to be reopened with a yearly grant of $15,000 from the city, the use of a municipal house, and admission to the city hospitals. This is the result of a favorable report upon the lady doctors' work in the public service by Dr. Archangelsky; and the ladies think he is well named.

AN ingenious burglar, under sentence for five years in the county jail, at Seattle, succeeded in deceiving the prison physician, who, under the impression that he had developed a case of small-pox, had him removed to the hospital, from whence he escaped. It is believed that medicine causing an eruption had been smuggled into the prison.

FATHER CONVERSE, rector of St. Clement's Church, refers, in a letter received from Africa, to the condition of the leper hospital at Cape Town; and he says that since the heads of the department have been changed and new quarters are begun, and the old cleaned and repaired, the hospital is in a generally improved condition.

TALE OF AN AUTOPSY.—Mrs. Kate Kunkle, who lives at 5045 Lancaster avenue, called on Deputy Coroner Dugan, Monday, and complained that the body of her husband, who died on Sunday at the Presbyterian Hospital, was mutilated, without permission having been obtained, by a post-mortem examination, and asked a thorough investigation of the matter.

AT the Alfred Hospital, Melbourne, the following report was made as to the results of treatment in typhoid fever: Cases in ordinary wards, mortality 15.9 per cent.; in municipal tents, first season in use, 11.2; second year in use, 19.5; hospital tents, partially used last season, 7.8; same, quite new, 3.1. The number of patients treated is unfortunately omitted.

IT is reported that when one of Barnum's elephants gave birth to its young, some years ago, the placenta did not come away of itself, and the mother placed herself over the short post to which she was tied, and by bearing her weight on this post expressed the placenta from the uterus and vagina. This would seem to show that Crede's method was not wholly original with himself.—*Practice.*

THE cholera shows no signs of abatement at Jeddah. There are one hundred and seventy cases of the worst type of the disease in that city. The authorities have forbidden pilgrims who have been to Mecca to embark at Jeddah. Troops have been sent to guard all points on the Red Sea where persons from Arabia are likely to land. Cruisers assist in maintaining the cordon. The mortality continues about one hundred daily.

THE remains of a number of Hungarians were found in a brine pit, where they had been thrown forty-one years previously. The bodies were so well preserved that they could have been utilized for anatomical study. The salt had penetrated the tissues and was found deposited in the interior of the body. This shows how readily substances in solution pass through the skin, and explains the beneficial effects of mineral baths on the internal organs.

THE following were the operations of the Woman's Hospital during July: Patients treated in wards, 126; discharged, 75; new patients treated in clinic, 506; gynæcological, 205; medical, 134; surgical, 70; eye, 64; ear, throat, and nose, 75; electrical, 50; dental, 28; total visits to clinic, 2,533. New patients treated at home, 46; visits to out-patients, 229; births in hospital, 15; operations in house and clinic, 58; prescriptions compounded, 2,118; nurses in service, 46.

THE International Medical Congress closed its sessions on Saturday last. It agreed to meet at Rome in 1893, the proposal to meet in Chicago being refused. Six hundred and seventy-three Americans were present as delegates, and many of them read valuable papers. That of Dr. Horatio C. Wood, of the University of Pennsylvania, on "Anæsthesia," appears to have attracted great attention. During the week the delegates had a constant round of feastings and ceremonies whenever the scientific discussions were not in progress. Mr. Phelps, the American Consul, gave a dinner on Saturday night in honor of Surgeon-General Hamilton, and other army and navy surgeons.

CHIEF OF POLICE CROWLEY, of San Francisco, who has been at the head of the Police Department for eighteen years, has filed a strong indictment against the Chinese of that city. He says the Chinese there commit more crimes against the law, in proportion to their number, than any other race or community, and the detection of the perpetrators of such crimes is more difficult than the detection of criminals of any other class, because Chinamen refuse to disclose the identity of their criminals. They have no regard for the obligations of an oath, and are becoming more vicious and immoral year by year. The chief favors the removal of the Chinese quarters.

PATENTS GRANTED:—

TREPHINING UNDER HYPNOTISM.—It is not generally known that Dr. A. B. Shaw trephined a man in this city, on May 15 last, while the subject was under hypnotic influence. The case was one of traumatic epilepsy, Jacksonian convulsions and hemiplegia existing. Dr. Benno von Steinmetz hypnotized the patient, and the operation was successfully performed before quite a large audience of physicians at St. Mary's Infirmary. The operation lasted one hour. Chloroform or ether could not be administered with safety on account of the heart and kidney lesions which existed. This case is one which, so far as we know, is an unique one of its kind.

—*St. Louis Med. and Surg. Jour.*

MONKEYS ATTACKED BY INFLUENZA.—Like the horses of Vienna and the cats of New Zealand, says a foreign writer, the monkeys of Southern India are numbered among the victims of influenza. A correspondent at Kurnul gives a harrowing account of how the epidemic has spread among the monkeys of the district. The animals were quite conspicuous one day by their absence, so that everything left out to dry on terraces was undisturbed—quite an unusual experience. Next morning they were seen in groups here and there, some coughing terribly, others reeling like drunken men, and then, later on, "the unpleasant stillness that reigned under the trees which afforded them shelter, was often disturbed by the crash of a heavy monkey coming precipitately down to the ground to die."

DURING July St. Louis reported 826 deaths; the annual rate per 1,000 being 22. The principal causes were:

Diarrhœa	144
Inanition	64
Phthisis	58
Marasmus	52
Convulsions	37
Heart diseases	34
Accidental	34
Pneumonia	27
Old age	27
Malaria	24
Meningitis	23
Bright's disease	23
Diphtheria	15
Cancer	15
Heat stroke	13
Typhoid	12
Apoplexy	9

THE *Medical Record* calls attention to the variability in the doses of the hyoscyamus alkaloids, and the consequent danger in prescribing them. Brunton gives a variation for hyoscyamine of from $\frac{1}{60}$ grain to 1 grain. Amosphous hyoscyamine is a mixture containing a little hyoscyamine and more hyoscine. Physicians should always specify the crystalline, and the amorphous should not be used at all. Of the crystalline hyoscyamine the dose is gr. $\frac{1}{120}$ to $\frac{1}{60}$; and of hyoscine the same. We have obtained very marked effects from the administration of $\frac{1}{100}$ grain of hyoscine hydrobromate; effects which were unmistakable.

THE American Rhinological Association will hold its Eighth Annual Session at Louisville, Ky., Oct. 6th, 7th, 8th.

All leading subjects relating to nasal and naso pharyngeal diseases will be opened for discussion by a leading fellow of the Association. The medical profession is cordially invited to attend.

The Secretary, Dr. R. S. Knode, Omaha, Nebraska, will furnish any information to physicians desiring to become members.

PHLYCTENULAR KERATITIS.[1]

By C. W. TANGEMAN, M.D.,

Assistant to the Chair of Ophthalmology at the Medical College of Ohio.

THE frequency of corneal diseases is exceeded only by diseases of the conjunctiva; while the interest at stake to both physician and patient is certainly greater in the former class of trouble. We will select for our consideration in this paper, a given type of corneal inflammation, since the subject generally would be entirely too tedious.

Corneal diseases, for the sake of ready conception, are divided into three great classes: 1. Infiltration. 2. Abscesses. 3. Ulceration.

The disease that we want to consider here, belongs to the first classification. It is distinctly an infiltration between the layers of the corneal tissue, and if you will indulge me for a few minutes I will refer to the anatomy of this structure very briefly.

If you will make a section through the various layers of the cornea, and place it under the microscope, you will see a picture much as is represented here in this drawing, though it is somewhat diagrammatic. There are five distinct layers; the first, made up of four or five layers of epithelium, as you see here, the second is the anterior elastic lamina, or "Bowman membrane," on which the epithelial layer rests. It is made up of connective tissue and is inseparable from the third layer, or the corneal tissue proper, called the "Substantia propria." It is made up of small bundles of fibrils, regularly arranged, so as to permit of spaces and interstices between them, which act as lymph spaces or channels. Fourth, we have elastic membrane, again the same as anteriorly, and resting on the fifth layer, which is made up of endothelium.

The cornea is an extra vascular structure, and depends on the lymph circulation for its nutrition. The nerve supply is quite rich, the larger trunks splitting up into minute fibrillæ, and ending in the epithelial cells of the first layer. The anterior layer is constantly shed and reproduced, so that if an abrasion should occur, the loss will soon repair. Nature has provided a barrier against destructive processes in the presence of the anterior elastic lamina; this layer is not reproduced, neither is the third layer. If the disease breaks down these two layers the repair is by cicatricial tissue, which is always opaque. The point that we wish to make here is that when the pathological process extends beyond the superficial layers, an opacity of the cornea is the consequence. Phlyctenula, means bubble up, forming a tumor under the epidermis. In this connection it is forming a tumor under the first, or epithelial layer of the cornea.

The very great difference between infiltration generally and the specific one referred to to-day, is as the name indicates; it is very superficial, the infiltration is chiefly between the first and second layers, as I have attempted to represent in this drawing.

Pathology.—According to the observation of Ivanhoff there is a subepithelial exudation of fluid, caused by an irritation along the branch of the fifth nerve, as it passes to the epithelial layer, causing an elevation or a bubble. There is a collection of round cells, at the end of the nerve, and this forms the typical phlycten. The infiltration may extend deeper and the haziness of the cornea become greater. Should, for some reason, the infiltration become so extensive as to disturb the arrangement of the substantia propria, or the nutrition of the structure be interfered with, causing a breaking down of the various layers, an abscess or an ulceration, and an indelible opacity will result.

Phlyctenular keratitis is circumscribed and not very extensive, but secondary changes may set in and give us a picture much modified from the one just described. The epithelial covering is very fragile,

[1] Read before Ohio State Medical Association, June 6, 1890.

and we have resulting an ulcer which, in certain patients, and under proper conditions, may be difficult to treat and endanger sight.

Variations.—Many subdivisions wholly dependent on the fact that the changes caused in the cornea and the various structures of the eye-lid, which naturally follow as a consequence of inflammation of the cornea, are not always the same in different patients, or under different circumstances in the same patients.

This disease is almost distinctly a disease of childhood, seldom observed before the age of two years, and found only under one circumstance after the age of eighteen or twenty. It may appear in one or both eyes at the same time, but usually one eye is involved first. Scrofula, as was once supposed, has nothing to do with the cause of this disease, but it runs a very tedious course in children belonging to this class. It is not often that we see a typical phlyctenule developing, despite the frequency of its occurrence since the many changes that are produced so readily by surroundings or constitutional influences.

A process that appeared quite typical at the onset, extends to the deeper layers of the cornea, and danger of perforation and prolapse of the iris is imminent. On the other hand, instead of remaining circumscribed, the process extends, and a corneal opacity covers the papillary area, which may remain permanently.

There may be but one vesicle situated at the sclero corneal junction, or there may be so many as to encircle the entire cornea, as it were, with a fringe. This is noticed more frequently in the colored race, which seems specially susceptible to this disease.

The vesicle may appear centrally on the cornea and pass through the various stages and disappear, and not show a trace of blood-vessels, while in another attack in the same patient the process is accompanied by the formation of blood-vessels that cross the sclero corneal border and reach the seat of inflammation.

Causation.—Little can be said about the causation of this disease, unless we accept the theory recently advanced, that it is due to a micrococcus. At any rate the disease can be brought about by inoculation. That constitutional taints and surroundings play a modifying rôle, cannot be denied, but only in a very limited number of cases is it observed, and only in these cases is constitutional treatment required.

In some patients, attacks of phlyctenular keratitis come on quite frequently without apparent cause, unless it be that they are using their eyes. Their eyes are on a strain, caused by some refractive error or muscular asthenopia. This once remedied, the patient makes a rapid recovery, and may never have another attack of the disease. These cases are simple. The class of cases giving the physician most worry and anxiety, are those in which the child (it may be well nourished and perfectly healthy), develops, aside from the local inflammation, a certain chain of nervous symptoms. The lids are spasmodically closed, so completely as to resist all of the efforts of the physician to pull them apart. When the cornea is exposed you will see a circumscribed, gelatinous looking mass, varying in size from a grain of mustard seed to a hemp seed, slightly elevated above the surrounding cornea, which has a bluish-hazy tint, due to infiltration. A leash of blood-vessels are seen to cross the sclero corneal junction and run to the point of irritation. This process may grow or a second phlycten may develop, giving to the cornea the appearance of pannus.

This disease is known as one of the sequelæ of acute infectious diseases, especially measels. You will have observed that this disease occurs nearly always in children only. Mucous membranes are very susceptible to inflammation in childhood, especially is this the case in the acute infectious diseases. The anterior portion of the cornea, or the first layer, is histologically the same as the conjunctiva, and it is the writer's opinion that the process on the cornea is different only in as much as the modified tissue makes it necessary. If we accept this view, then the same cause producing the inflammation of the mucous membrane of the mouth, nose and lungs in measles, also causes phlyctenular conjunctivitis and keratitis. Filth, negligence and bad hygiene, undoubtedly have an influence in this disease, but do not act as causative, as has heretofore been supposed.

Symptomatology.—The symptoms of this disease are characteristic, while the disease may run an acute course in one instance and a chronic in another, yet the subjective symptoms are so typical that a diagnosis could be made as the child is passing through your door-way on its mother's arms.

The most marked and obstinate symptom is photophobia—sensitiveness to light. It was supposed that the sensitive nerve endings, as in the process just described, we had a good explanation of this symptom, but in some of the worst cases the amount of photophobia, and the extent of corneal damage, is so out of all proportion, that in my estimation we must look for another explanation. A great deal of the nervous element seems to be present. There is a spasmodic contraction of the orbicular muscles. The frontal and orbital muscles are firmly contracted, and it is often quite difficult to even get a glimpse of the cornea.

Anæsthesia, external canthotomy, plunging the child's head under water, are suggested by the older writers as means of breaking the spasm. Tearing is profuse, when the lids are pulled slightly apart a gush of water takes place, as if you had caused a loss of the aqueous humor. In older children you will find that they are constantly mopping their eye. This secretion is many times so acrid as to cause excoriation of the integument of the face about the eyes, nose and lips. The external angle of the lids is always excoriated, and when the lids are forcibly pulled apart bleeding takes place, and great pain is caused. The eye-lids are swollen and puffy, caused by disturbance of the circulation when the lids are spasmodically contracted for days at a time. Now let us instil a few drops of a 5 per cent. solution of cocaine, and in a few moments we can inspect the eye-ball. The conjunctivæ of the lid and bulbus are reddened, but you can soon see that the cause of the redness is not a conjunctivitis, but simply an extension of the irritation from the cornea.

Most frequently we find the recent seat of the disturbance at the sclerocorneal junction. It may be but a small abrasion, or extend as an abrasion along this border for some little distance, or we will find a distinct vesicle slightly elevated looking as if it had a gelatinous base, situated at the margin of the cornea and possibly fringing its entire circumference. Or one or more vesicles may be situated on the cornea. When the phlycten is situated on the cornea, as a rule, a bunch of blood-vessels cross over at the nearest corneal border, and run towards the vesicle. These vessels are new formations and are quite superficial. Sometimes the phlycten has clear cut edges, and then again a margin of infiltration extends into the corneal tissue for quite a distance. It is more frequently that we see the phlyctenular process as an ulcer with a dirty base than a vesicle, since the covering is quite delicate and is easily broken. These

many variations that have been so briefly referred to are no doubt produced by the same cause; but the idiosyncrasies of the patient, his habits and surroundings are the cause for the difference in appearance.

Prognosis.—The prognosis of this particular form of corneal disease is not so unfavorable as might first appear. The process is one involving the superficial layers, and while the infiltration may be quite extensive, the cloud like opacity disappears quite easily. Should an ulcerative process set in and extend to the deeper layers, repair is by cicatricial tissue, and an opacity more or less dense will remain permanently. It is in this manner that perforation of the cornea, with all its unpleasant symptoms, occurs; but this is exceedingly rare. It is easily comprehended that only when an opacity is centrally situated or extends into the pupillary area, does it disturb vision; and, if you prevent an extension of the disease to the center of the cornea, or limit the pathological process when found centrally to the superficial layer of the cornea, vision will not be affected by it. Relapses are not infrequent, and may continue to annoy the child for years; in older persons we find that these are the ones benefited by glasses.

There is another point which we must refer to in this connection, namely, the sluggishness of repair. It may require months of patient treatment to repair the damage done in two or three days. The newly-formed blood-vessels get smaller and finally disappear; the general infiltration is cleared up, leaving a clear-cut, sharply-defined, grayish opacity at the seat of disease. The redness of the conjunctiva disappears as the disease runs its course.

Differentiation.—It is not difficult to diagnosticate this disease. Should the corneal opacity be dense and centrally situated, there is danger of mistaking it for cataract, but only by those not informed. In the variety known as Bushel Keratil of the Germans, where there is a profusion of blood-vessels developing on the cornea, all pointing to a central point as an apex, there is danger of mistaking the disease for pterygium.

Treatment.—In the treatment of this disease there are three points that we must bear in mind: first, the ætiological factors in the case; secondly, the corneal process itself; and, lastly, the accompanying symptoms. If you should discover the cause of the disease in any case, while treating it during the recurring attacks, it would be an important factor, since the course of the disease could be very much shortened, if not prevented altogether. For example, if we should discover that recurring attacks of phlyctenular keratitis are caused by some refractive trouble, its correction is, likely, all the treatment that is required to prevent further trouble. What interests the patient most is whether the corneal opacity can be removed. When centrally located, it materially disturbs vision; while it is a deformity at best. Constitutional remedies are but seldom indicated. Should we discover a malarial element or a periodicity, antiperiodics are indicated. Sulphide of calcium in half-grain doses, repeated two or three times daily, is often of great service in checking this disease, especially when the submaxillary and the cervical glands are involved, or when there is ulceration of the cornea. The only drawback with this agent is you can never tell beforehand whether it is indicated or will be of any service in a given case. Antiphlogistics are never indicated. Local applications are made for two purposes: first, to control the inflammation of the cornea and lid, and then to hasten repair. Eserine, the active principle of Calabar bean, will undoubtedly be found to be more effective to accomplish these two purposes than any other agent. Irritants are to be strictly avoided as only aggravating. Atropine is only of service where a refractive error is the cause of the disease. It increases intra-ocular tension, and is therefore often inadmissible. After the acute symptoms have passed away, our aim should be to increase the absorptive powers of the cornea, to relieve this tissue of its infiltration or engorgement. The sooner this is done, the less permanent damage is done to the cornea. Cocaine is a valuable agent in this disease; it lessens intra ocular tension, and relieves much of the pain and sensitiveness to light that these patients complain of. Hot water applied to the closed lids every four hours, for a few minutes at a time, is often found to give the patient much relief. When the tearing has ceased, no better remedies than the mercurials in ointment form can be employed, and preferably the yellow oxide. This applied but once a day. If there is any virtue in hastening absorption by the use of irritants, then we have combined in the above remedy all that is elegant and efficient. The question is often asked, How long must treatment continue? It is dangerous to risk a prognosis; but you will always find that it is more easy to remove a recent opacity, occurring in a child, than one of long standing, or when found in an adult.

A few years ago the author pointed out the usefulness of the fluid extract of jequirity in these cases, where ulceration has set in and the healing process is very sluggish. A single application seems to be sufficient to stimulate and hasten repair.

A FEW MORE REMARKS ON DERMATITIS HERPETIFORMIS.

By A. RAVOGLI, M.D.,
CINCINNATI, OHIO.

SINCE Duhring, in 1884, called the attention of dermatologists to a group of eruptions of the skin, under the name of dermatitis herpetiformis, the interest in these eruptions has greatly increased, because many affections of this kind could here find their right nosological place in dermatology. Many of these cases were formerly confounded with erythema multiformis; others with herpes iris; others with pemphigus; impetigo herpetiformis Hebræ remaining a peculiar eruption, out of any definite nosological class. As the bulla was characteristic of pemphigus, so every bullous eruption was characterized as such, and, on account of the pruritus, the adjective of pruriginosus was added.

Duhring's work consisted in definitely establishing the general symptoms which constitute the type of these eruptions, and thus referring them all to one group.

These group symptoms are as follows:

1. Polymorphism of the eruption
2. Paresthesia;
3. Chronic course and relapse;
4. Relative general good feeling.

Certainly, the disease is not a new one, for we find many descriptions of eruptive diseases of this kind scattered in the books of different authors, called with different names. To day these various eruptions are to be referred to this type dermatitis herpetiformis. So we find herpes phlyctænoides in Chaussit, 1852; pemphigus circinatus in Rayer, 1828; pemphigus chronicus in Rach, Jr., 1841; pemphigus compositus, herpes pemphigoides, or pemphigus herpetiformis, in Devergie.

Cazenave[1] had already remarked that pemphigus sometimes is accompanied with different eruptions, like herpes and prurigo, and in this case the affection resembles pompholix pruriginosus Willan, where the patient is troubled with itching and burning sensations. In these cases small vesicles are mixed with large bullæ, aggregated into groups, resembling herpes phlyctænoides, while large bullæ of pemphigus are scattered on the cutaneous surface.

In Bazin, under the article arthritides bullosæ, we find a description of two varieties of bullous eruptions, viz., pemphigus arthriticus and hydroa bullosa, where he includes all the symptoms of dermatitis herpetiformis.

Auspitz[2], under the head of neuritic dermatoses, established a group of eruptions which he named inflammatory trophoneuroses with acyclic course. He gave to this class of eruptions the generic name of erythanthema, which he divided in two families, viz., those affecting the skin superficially, and those affecting the skin deeply. He divided the last family into species vesicular, pustular, and bullous, including herpes circinatus, iris, annulatus, herpes phlyctænoides. As herpes impetiginosus he understood the disease described by Hebra as impetigo herpetiformis.

It would be superfluous for me, in the brief space allowed, to go on to review all the authors who before Duhring described cases of this disease under one name or another, but I must refer the reader to the beautiful and complete work of L. Brocq, on Dermatitis Herpetiformis Duhring.

Brocq differs with Duhring as regards the name, and he prefers dermatitis polymorpha pruriginosa chronica à poussées successive. It is a question of nomenclature, but the form remains the same, and we must be grateful to Duhring for having traced the principal symptoms which form the characteristics of this peculiar affection. The name of dermatitis, inflammatio cutis, inflammation of the skin, seems to be rightly applied, as vesicles and bullæ are situated on a red halo; and this redness precedes the spreading of the eruption. The adjective herpetiformis gives the idea of vesicles with a tendency to aggregation.

There is no question that one of the most remarkable characteristics of this affection is the disposition to relapse; when a spot is nearly healed up, a new crop of vesicles or bullæ comes up again. The genius of relapsing is so characteristic of this affection that, as Unna remarked,[3] the cases referred to by Brocq, where no relapse had been seen, ought to be excluded from this group.

Paresthesia, perversion of the sense of touch. This is the itching sensation, and is the dominant symptom in this disease. The patient complains of an itching and burning sensation together, which often prevents him from sleeping, and obliges him to scratch his thick and infiltrated skin. This symptom is so important as to distinguish a case of dermatitis herpetiformis from a case of a true pemphigus. The restlessness and the continuous scratching of the patient affected with this disease contrasts a great deal with the quietness and the dread of changing position in the patient affected with true pemphigus. According to Unna, pemphigus pruriginosus is to be taken out of the group pemphigus, and is to be comprehended in the group dermatitis herpetiformis. The perversion of the sense of touch, revealed by the itching, shows the disorder in the sensitive nerves, which is the causa proxima of this disease.

Polymorphism of the exanthema forms another characteristic of the disease. Papules, vesicles, bullæ and pustules are found together in a striking way; but we can assert that the predominant feature is the vesicle and the bulla. I seldom saw a true pustula, but mostly the vesicles or bullæ filled up with a turbid and purulent exudation. This remark has already been made by Brocq. The condition of general health maintained in this disease must be considered only as relative. The patient does not lose his appetite, but on account of the itching sensation loses a great deal of sleep, and, in some cases, wastes away considerably.

To give a practical example, I will take the liberty of reporting, as briefly as possible, a case of dermatitis herpetiformis, which I had the opportunity to study from its very beginning.

A gentleman, N. S., fifty-three years old, in the best of health, who had never had any disease of consequence, in very good financial condition, called upon me in April, 1889, complaining of an itching sensation all over his body, but more intense on the chest and on the arms. The skin, white and smooth, was furnished with an abundant *panniculus adiposus*, and did not show anything with the exception of a few small red maculæ in the middle of the chest. A mild alcoholic solution of carbolic acid was prescribed, for the purpose of diminishing the itching sensation. A few days after, the patient came back complaining that the itching sensation was still more intense, and at this time small papules, like in eczema papulosum, were scattered on the chest and on the shoulders. Under the impression that I had to do with an eczema papulosum, a salve, consisting of oxide zinc, subnitrate bismuth, carbolic acid and vaseline, was given to be rubbed on the eruption. A few days after, a papular eruption was spread all over the body and on the limbs. The skin was red, and of the papules, some were small, of the size of a grain of millet, and some larger, polygonal in shape, and depressed in the center, resembling exactly the papules of lichen ruber planus. At this time I had the idea that the case was one of lichen ruber scarlatiniformis. I prescribed then Asiatic pills, from two to four a day, and baths with water wherein some wheat bran had been boiled, assuring the patient that in a few months everything would return to the normal condition. From this time I did not see the patient. Three months after, I was called in consultation to see the same gentleman. All his body was covered with bullæ filled up with clear serum, ranging in size from that of a pea to that of a hen's egg. Where the bullæ were broken, large excoriations remained. In the places where bullæ had already healed up, the skin was dark brown in color; thickened and large flattened papules were raised above the level of the skin.

Bullæ were also coming on the mucous membrane of the lips, of the mouth, and of the throat. These bullæ soon broke, leaving excoriations. The patient was extremely nervous and excitable, but his appetite was relatively maintained, and he could take a sufficient quantity of nourishment.

The patient would get better from time to time; his excoriations would heal to a considerable extent, and we would all begin to hope for recovery, but relapse was seen to occur and was always preceded by slight elevation of temperature.

At one time the whole body was one sore; bed clothing and everything stuck together. We feared reabsorption, and it was necessary to put the patient

[1] Abregé pratique des maladies de la peau, 1847.
[2] System der Hautkrankheiten. Wien, 1881.
[3] Ueber die Duhring'sche Krankheit und eine Form derselben. Monatshefte f. Pract. Derm. B. ix, No. 3.

into a continuous bath. This, however, could only be used at intervals, as the patient complained of chilliness, and it was necessary to have the water at the temperature of 98° F., which made him weak and produced congestion in the circulation of the brain. The continuous bath, in spite of all the difficulties, acted very satisfactorily. The eruption of new bullæ subsided, and the extensive excoriations healed up considerably in about three weeks' time. But after three weeks we were obliged to quit the bath, because this chilling was so bad that the patient could not stand any more. The patient was now anointed with different salves, vaseline and salicylic acid, olive oil and carbolic acid, always in very mild proportions. New bullæ continued to appear, which became rapidly purulent, and the patient began to show symptoms of pyohemia. Fever ranged between 101° to 103°; pulse very weak and over 120, and his life was in great danger.

Abundant doses of quinine reduced the temperature, and the large discharging sores were dusted with iodoform powder, and covered then with iodoform gauze. This treatment helped him; the fever disappeared, the excoriations gradually healed up, so that the patient was able to get up and go out riding. When I left the patient, he was almost well; no new bullæ were coming, and there remained only some itching sensation. His sleep was tolerably good, appetite excellent. He wished to go to some resort, and chose Old Point Comfort.

I must remark some peculiar features of the general symptoms. The urine had been carefully examined every few days, and it was found always of a normal acid reaction; never could any trace of albumen be detected; urates and phosphates were somewhat in excess. The most interesting symptoms were revealed in the nervous system. At times the gentleman was somewhat stupid, taking but little interest in surrounding things; at times he was irritable; and for some time was slightly delirious during the night. His sleep was very agitated; he slept only a few minutes at a time, and no hypnotic could produce a few hours of rest. Night-sweats were very profuse, especially late, when he was improving.

In order to give a complete account of the case, it must be related that the gentleman had another relapse at Old Point Comfort. He was not satisfied in the treatment and he left for Philadelphia, where he went under the care of Duhring. From Philadelphia he went to New York, having another relapse, and put himself under the treatment of Elliot and Bulkley. He came back to Cincinnati, with still another relapse, and is now again under my charge.

It will be seen that the general feeling of well being, which is said to be characteristic of this disease, is to be taken with a grain of salt; that, indeed, there are many interesting symptoms affecting the general health, and more conspicuously the nervous system.

In the beginning I called this case pemphigus pruriginosus, and I find that it has some likeness to the case lately published by Dr. Henry G. Piffard[1] under this same name. However, I do not see any reason for leaving these cases separated when we can refer to one group diseases which have the same symptoms in common and have nothing to do with real pemphigus.

Until here I have spoken of dermatitis herpetiformis, which has been more frequently observed, as an eruption of papules, vesicles, and bullæ, with a disposition like herpes, disseminated on the surface of the body, which, although of long standing, shows in its relapses a kind of acute course.

I wish now to call your attention to another case of the same kind, in which the eruption runs an exceedingly chronic course, and has a kind of progressive way of spreading over the skin by continuity.

This is a lady, Mrs. E. Z., fifty-nine years old; she has always enjoyed good health; she is five feet tall, one hundred and seventy pounds' weight, fleshy. Her skin is white and delicate, panniculus adiposus abundant. She has been always in very good financial condition, belonged to the highest society. Four years ago she lost her husband under the saddest conditions. After the death of her husband, many of his investments were found to be reckless. The loss of her husband and her financial troubles threw her in a deep grief. About three years ago there appeared on the index of the left hand an eruption in form of vesicles filled up with purulent matter. The eruption spread slowly over the back of the hand for a time, then stopped; but the skin remained thick and of a brownish-violet color. A few months afterwards an eruption of vesicles appeared on the lips, around the ears, and on the temporal regions and the toes, and the back of the right foot. At this time I was called in consultation by her family physician. The surface was completely covered with thick, yellow-brownish crusts, having the appearance of an eczema impetiginosum. After having removed the crusts with applications of olive oil, the surface was found affected in large spots, in the center of a dark-brown color, with papules and pustules scattered over, and in the periphery deep excoriations in a semicircular disposition; itching and burning sensation accompanied the eruption.

Still under the impression that I had a case of eczema to deal with, I applied unguentum diachylon Hebra, spread on muslin. The result of this application was not satisfactory, as it brought out many more vesicles, which were early broken, and left the surface more excoriated. The disease spread upon the periphery of the plaques in form of a row of vesicles upon an inflamed basis.

Vesicles and pustules of the size of a millet seed appeared on the tongue and on the mucous membrane of the mouth and of the nose. These soon broke, causing serous discharge from the mouth and from the nose.

At this time a mild salve of resorcin was used (half drachm in one ounce of vaseline); but the burning caused thereby was so great that it was necessary to stop its application immediately. Internally, solutio Fowleri arsenici, in doses of from six to fifteen drops a day, was prescribed.

New conglomerated vesicles were continually developing at the edges, forming semicircles. The epidermis covering the vesicles was easily removed, leaving the excoriations in the form of crescents, extending on the parietal region. Another spot developed in the same way on the occipital region, running downward on the back of the neck. Every active remedy had proved unsatisfactory, increasing the irritation and bringing out new crops of vesicles; so we resorted to indifferent means, so as only to cover the skin and protect it from the contact of the air. The surface discharged a great quantity of serous fluid, which stuck the hair together, took an offensive smell, irritated the healthy skin with which it came in contact, and caused an unbearable itching sensation. The surface, therefore, was washed twice a day

[1] *Journal of Cutan. and Gen.-Urin. Diseases.* New York, April, 1890.

with a mild solution of carbolic acid, and, after having been dried as well as possible, a salve containing subnitrate of bismuth, oxide zinc, in the proportion of half a drachm to one ounce of vaseline, with ten drops o carbolic acid, was applied with a brush. In this way the inflammation diminished and the excori ations healed up. The surface of the skin, however, remained highly pigmented, showing a dark-brownish color, and because of abundant granulations, it presented flat papules, similar to those seen in impetigo herpetiformis; hence the name given by Auspitz,[1] herpes vegetans.

The affection was now at a kind of stand-still; the excoriations were in great part healed up, the discharge of serum nearly stopped. Once in a while a few small vesicles would appear on the old affected spots. As it was in summer time, the patient thought that, if she went to some watering place, she might derive some benefit from the change of climate. I therefore lost sight of the patient for about nine months. I must express my thanks to Dr. Jos. Ransohoff, who called me again to see the case.

The eruption at this time had affected the forehead, the eyebrows, the eyelids, the nose, both cheeks, lips, and chin; extended over the whole neck, down upon the breast, and backward on the shoulders—representing exactly a lace fichu. The skin was dark, brownish-red, slightly swollen, with large, flat papules, lighter in color, raised above the level of the normal skin. At times, crops of miliariformis vesicles and pustules appeared, scattered over this affected skin. The edges were raised above the level of the normal skin, showing an uninterrupted row of vesicles, whitish, pulpous, from the size of a millet-seed to that of a split pea, on a red, inflamed halo, which is extended upon the healthy skin. The whole resembles to some extent a burn produced by hot water. The slightest contact or rubbing removed the epidermis, and left an excoriation in semicircular form: neatly cut, as if it had been done with a penknife. The itching sensation was unbearable, but the general health of the lady was relatively good; appetite and digestion good; the bowels regular. Sleep was disturbed by the itching sensation; but, in spite of it, the lady got some rest at night, at intervals.

It is worthy of remark that, at each new eruption, the patient complained of some chilly sensation towards evening; and, when the eruption was spreading so badly, she had some fever. New spots are now coming; one in the middle of the breast, and one under the axilla. A small bulla of the size of a pea is the beginning, and this soon dries up, forming a slight brownish crust; then vesicles appear around the first, forming the spot, which grows and spreads regularly.

At present I am treating the patient with only ichthyol. She takes from thirty to forty drops of ammon. sulphoichthyol. a day, internally; and, externally, I paint the surface with a lotion of ichthyol, aqua rosæ, and glycerine, equal parts. At first it caused some burning sensation, but soon it diminished. The itching sensation has diminished a great deal and the swelling is going down. Few new vesicles and pustules are coming, and the old papules are slowly diminishing. The edges are still excoriated and discharging seropurulent matter. The face is covered with pasta zinci mollis with ichthyol, according to Unna.

Looking over the literature of this disease, I find that there is an analogy between my case and a few cases which have been reported by Brocq in his dermatitis polymorpha pruriginosa chronica a poussée's successives, varietas gravis. The first, No. 29, from Dr. Lailler, the eruption, spreading slowly, covered the whole body, and had a fatal end. Two other cases, under the numbers 31 and 32, the first from Bazin and the second from Rayér, have a great likeness to the one under consideration.

The cause of this disease is still in darkness, but without doubt it lies in an alteration of the nervous system, as is the case in herpes zoster. The disease is not contagious, and the fluid of the vesicles inoculated in rabbits has never given any results. The lady patient, of a very irritable nature, suffered for years under a great grief; the moral trouble may have influenced her nervous system.

Brocq would not grant too great an influence to moral impressions, but would rather attribute the cause to an arthritic diathesis. In both our patients there was no sign whatever of rheumatic diathesis, although both were used to very high living. I return to my first idea, that the cause of the disease is to be found in the nervous system, which opinion is also maintained by Bulkley, Lineing, Alfred Wiltshire and Wyndham Cottle, for herpes gestationis.

The first symptom of this disease consists in the perversion of the sense of touch, paresthesia, itching sensation, which shows that the sensitive nerves of the skin are affected. The itching and burning sensation in some cases is limited to the place of the skin which is affected, in others is spread all over the body. The patient cannot stand the pruritus, and scratches his skin to get some relief from his troublesome sensation. In our first patient the itching sensation was spread all over the body, but in the lady this was limited to the affected places, and preceded the new eruptive plaques. It seems that the paresthesia is the symptom which speaks most for an alteration of the nervous system. If the itching sensation follows the eruption, then it must be believed that the infiltration and the anatomical alterations in the texture of the skin were the cause of the pruritus, but in our cases itching sensation was the first symptom and preceded any eruption.

The form of the eruptions differs according to the variety of dermatitis herpetiformis. In a general way, we may say, that it begins with enythematous plaques, which rise into papules, or the epidermis is filled up with serous fluid in form of vesicles and bullæ, or with purulent exudation, vesico-pustules and pustules. The texture of the skin is considerably altered; it remains infiltrated, thick, hard, highly pigmented and congested, of a brownish-violet color. In consequence of the vesicles, of the bullæ, and of the pustules, excoriations and crusts remain on the diseased skin. In the lady we found a considerable swelling and acute œdema of the eyelids and of the face when the eruption spread on that region.

The color of the erythematous plaques in the beginning is vivid, and disappears under the pressure of the finger, and has nothing to do with the brownish-violet color, which we find in the infiltrated plaques, where the eruption had its seat.

The spreading of the eruption is different in the various cases. In our first case the bullæ appeared all over in large bunches, affecting one day the genital and the gluteal region, another day the limbs and the chest, and so on until the whole body was covered with bullæ. In the second case, however, the disease spread with the greatest regularity, and the new eruption appeared on the edges, while at times relapses of pustules and vesicles occurred scattered irregularly on the old infiltrated spots.

[1] *Archiv. f. Dermatologie*, 1868.

In a recent relapse in the first case we can notice small, reddish papules, surmounted by small vesicles, of the size of a pin head, aggregated together like sudamina, spread over large regions of the body, while small pustules are scattered on the limbs. In the second case, the vesicles are no larger than a millet grain to a split pea, brilliant like pearls, disposed in circles on the edge of the spot. The vesicles are easily broken, and the slightest contact removes the epidermis in form of shreds, leaving the corium uncovered. It is remarkable that any irritation, or any pressure, is liable to bring out a new crop of vesicles. Vesicles come often on the occipital region, which rests on the pillow. Just in the middle of the breast, where the springs of the corset rub, a new plaque is now coming. Another plaque of numerous vesicles is now formed under the armpit, where the two surfaces of the skin come in contact. Vesico-bullæ are frequently developed on the tip of the fingers of the right hand, from any attempt to sew, or stick a pin, or button her clothes.

Comparing the two cases, we see that both are of long duration, but in the first we see a tendency to acuteness, while in the second we see a tendency to chronicity. In the first, in each relapse there is a stormy appearance of vesicles and bullæ, while in the second we see the vesicles slowly formed, and slowly but surely progressing.

I cannot say much about the duration of the disease. Both our patients are improving; their general health is pretty good; appetite maintained, digestion fair, bowels moved regularly. The pulse is good, the heart in normal condition; no remarkable change in the chemical constitution of the urine; the patients did not lose much of their weight, and everything shows that the principal functions are in complete order. This removes any idea of fear for the life of the patients at present. The patients of Bazin and Bulkley were permanently cured. This encourages us, and we hope for the best.

What about treatment? While I was reporting the clinical history of the cases, I told what we were administering to our patients. A great many remedies have already been tried, but all without satisfactory results. Milk diet, alkalines, purgative mineral waters, tartrate of potassium, arsenic, iodide of iron, tonics, strychnine, belladonna, atropine, quinine, cinchonidin, ergotin, tinctura cantharidis, iodide of potassium, etc.

Iodide of potassium has been already condemned. In some cases the arsenite of soda seems to have done good, especially Hutchinson claims great benefit from it. In both our cases we found arsenic of no account, if not pernicious. The extract of ergot seems to have been of some benefit in our first case, but did not seem to be of any benefit in our second case. I am actually trying, internally, ichthyol in the lady, and we can say that it has been useful, as she is somewhat better. She takes sixty drops a day in three doses.

Externally, we can say that we have applied every thing which can be found in the dermatological formulary. Unguent diachylon Hebræ, unguent zinci benzoati, unguent resorcin, aristol, oleate of bismuth, oil and carbolic acid, liniment oleo calcarium covered with cotton, baths with amylum powders, etc., but all without satisfactory results.

I must remark that every time the unguent diachylon has been applied, more vesicles have come out. It seems to me that any slight irritant agent applied on the skin has increased the fury of the disease. I must state that I am treating the lady now with ichthyol; for the face, neck and shoulders I am using gelatina zinci mollis, with 2 to 4 per cent. of ichthyol. This has calmed the burning sensation, the itching is not so intense. The papules are flattened, and no new vesicles or pustules are coming on the affected places. The raw edges covered with this gelatine do not cause pain, and in some places are healing up. I think that this paste has given me more satisfaction than any other remedy used. For the head I am using now ichthyol, aqua rosæ and glycerine, equal parts; it does not irritate; many excoriations have healed up, and I feel encouraged to keep on in its use.

In our first patient, while under the treatment of Elliot, also ichthyol has been used in association with aqua calcis and oil of sweet almonds, and the patient improved considerably.

It seems to me that ichthyol has a peculiar sedative influence upon the final nervous ramifications. In several cases of pruritus, it has stopped the itching sensation, when every other remdy had failed. In many cases of nervous eczema, especially in children, a lotion of

℞.—Ammon sulfoichthyol . . . . . ℥ij.
Aq. ros., ...
Glycerine . . . . . āā ℥ss.

has given very satisfactory results. In the lady patient referred to, where any indifferent application caused burning and eruption of new vesicles, ichthyol does not produce discomfort, diminishes the itching, and the excoriations under the dark cover of the ichthyol seem to heal up faster.

A well-regulated diet is strictly necessary in the treatment of this disease. Our patient is now on an exclusive milk diet; coffee, tea, wines and liquors are strictly forbidden.

Anything which is capable of producing erythema or urticaria, like strawberries, clams, lobsters, etc., must be avoided. Meat alimentation must be greatly reduced. The more digestible food must be selected.

The bowels must be carefully watched and regulated accordingly.

With this case we have obtained some improvement of this interesting proteiform disease, which I dare to call dermatitis herpetiformis progressiva.

REPORT OF ONE YEAR'S WORK OF INTRA-PELVIC SURGERY FOR THE RELIEF OF INFLAMMATORY DISEASES.

A SUPPLEMENT TO TEN CONSECUTIVE CASES OF ABDOMINAL SECTION FOR THE REMOVAL OF THE UTERINE APPENDAGES, FOR THE RELIEF OF PELVIC PAIN, AND THE RECURRENT ATTACKS OF PELVIC INFLAMMATION.

By RUFUS B. HALL, M.D.,
Surgeon to the Cincinnati Free Hospital for Women, etc., Cincinnati, O.

I BELIEVE we can best utilize the time allotted us by a review of the work done in the past year in intra-pelvic surgery for the relief of inflammatory diseases peculiar to women. The cases here tabulated, eighteen in number, include all of the operations made for the removal of the uterine appendages by myself, taken consecutively since my report to this society last year, and are reported as a basis for thorough discussion of this important class of gynecological work. In no case was the operation made until the patient had been subjected to the best and most approved local and constitutional treatment for

many months, and, in many instances, years; and this treatment had failed. In several instances the patient, and those interested in her welfare, would not accept an operation until the case was regarded as hopeless by the attending physician. In no case, however unpromising, have I refused to operate, and all have recovered.

Considering the pathological conditions present in all of these cases, the strong adhesions to overcome, and the enfeebled condition of many of the patients, the results are all any one could ask. These results have not been attained with ease, and many of the cases gave me no small degree of anxiety for a number of days after the operations were made. I have no hesitation in saying that I could not make the report to-day unmarred by a death if I had not had the patients where I could give them careful after-treatment. It has been asserted that the after-treatment in these cases is nothing. My own experience is diametrically opposed to this assertion. As a rule, patients do not require prolonged treatment after these operations, but they require more care and attention for the first few days than other cases requiring abdominal section, except, perhaps, super-vaginal hysterectomy. Regarding the difficulties encountered in these operations, I can emphatically endorse the statement made by that eminent and brilliant young surgeon—Dr. L. S. McMurtry—in a paper read before the Southern Surgical and Gynecological Society, in November of last year. He said: "The operations upon the uterine appendages are among the most trying in the entire field of pelvic surgery. To remove pus tubes and adherent ovaries, buried in a mass of adhesions, and friable from cheesy degeneration and suppuration, is among the most severe tasks of operative surgery. Normal relations are destroyed by the exudation; the fingers must make a track to the floor of the pelvis, and blood and pus well up as the exploration and enucleation proceeds. The sight gives no aid; the work is done wholly with the two fingers deep in the pelvis."

This quotation fully coincides with my views regarding the difficulties of the operation of removal of the appendages in long standing inflammatory diseases. I am aware of the fact that these are trying times for men engaged in this special work. They have their way to make and their position to sustain against the many difficulties incident to the work, as well as against the failures of those who insist upon opening the abdomen because it is easy. We all know an uncomplicated ovariotomy is not difficult, but, on the contrary, is one of the easiest of the capital operations. But we must admit that the operation is a serious one, to be carefully performed after very careful consideration. We are to remember that very frequently what appears to be a simple and easy operation may eventuate in the most complicated condition; and this is the reason for the necessity of careful preparation and training in every detail that pertains to abdominal and pelvic surgery before the work is attempted, if one hopes to win the best result. A knowledge of the accidents that may happen is one of the best means of avoiding them. I have long since learned that before opening the abdomen no exact estimate can be made as to the gravity and extent of the complications to be met with in any given case. I am convinced that no man has a moral right to open a patient's abdomen unless he is prepared for any emergency which might occur, and is himself competent to deal with the conditions found on the spur of the moment, and in a surgical manner.

The success of abdominal and pelvic surgery is bounded and measured by the ability of the operator to overcome their many complications. In presenting this group of cases of tubo-ovarian diseases, as tabulated, you will observe that it illustrates the severest lesions met with in this kind of work. All the patients had suffered long and severely; all had suffered from peritonitis—not only once, but repeatedly. When salpingitis exists without suppuration, I do not believe, for that reason alone, an operation is justifiable until the patient has had the most approved local and constitutional treatment for many months. That this is the most judicious plan to pursue is proven by the fact that in many of these cases the patient is made more comfortable by treatment, and occasionally one gets rid of her symptoms, and is so much improved that an operation is not necessary. For these reasons all cases of chronic salpingitis should have a prolonged course of treatment before submitting them to an operation. But, after a prolonged and systematic course of treatment, if the patient continues to suffer great pain, and where the tubes, ovaries, broad ligaments, and intestines are soldered, as it were, into a single mass, an operation is indicated and justifiable, even if the existence of pus cannot be made out.

In cases 20, 25, and 27 the operations were made for the relief of these conditions. Case 20, which proved to be tubercular salpingitis, had been treated by a number of good physicians for five years. She had the benefit of a change of climate, yet she was constantly growing worse. She had three attacks of hæmoptysis within three months' time just preceding the operation. There was dullness on percussion, over the apex of the right lung, and daily exacerbation of fever for ten weeks just preceding the operation. She could not be out of bed for a whole day for many weeks, and was losing flesh and strength. She had suffered from repeated attacks of abdominal inflammation, and had constant pelvic and abdominal pain. The uterus was fixed by inflammatory exudations, and was exceedingly sensitive to pressure. It is not quite five months since the operation, and she is now in better health than she has been at any time since her illness commenced. She has gained eighteen pounds in flesh, and with it her strength has returned. I await the ultimate result with much interest.

Cases 25 and 27 were likewise chronic invalids, with constant pelvic and abdominal pains. They, like the preceding one, had suffered from repeated attacks of peritonitis. The uterus was fixed from inflammatory adhesion, and it was with the greatest difficulty that the appendages could be found and removed.

These three are the only ones in the whole series of twenty-eight that there was no pus to be found in the pelvis, yet the operations have restored them to health after all other measures had failed.

All the remaining cases had pyosalpinx excepting cases 3 and 24, which were abscess of the ovary. In many of these cases it was impossible to separate the adhesion without bursting the pus sac. In every case where this occurred, and in cases where there was much bleeding, the abdominal cavity was washed out with the gravity tube. Free washing out of the abdominal cavity need not be feared—the heat relieves the shock. I have constantly employed it, when necessary, since April 7, 1887, and have not seen a single case where it caused a single bad symptom. I irrigate until the water returns as clear as it was before it was put into the cavity. Although all

of the cases recovered, a number of them would not submit to an operation until they were *in extremis*. Let us turn for a moment to the other side of the picture. Since my report to this society last year I have seen four cases in consultation and advised an operation for the removal of pus-tubes, which was refused by the physicians in charge and the friends of the patients, because an operation involved danger to life. All of these cases died within a few weeks after the consultation. They all died from peritonitis, with every indication of a ruptured pus-tube. In but three could an autopsy be secured, and in all a ruptured pus-tube was found to be the cause of the fatal attack of peritonitis; and I have no hesitation in saying that the same condition existed in the fourth, but could not be verified because an autopsy could not be secured.

I refer to these cases to show that in cases of pus in the pelvis there is danger to life in the *so-called* conservative plan, or in the let-alone *plan* of treatment—as well as in that of operation—when, in this instance, with a mortality of less than 4 per cent., where every case presented was operated upon, except the cases mentioned which refused an operation.

In the cases refusing an operation the mortality was 100 per cent.

The following tabular reports of the two series of cases operated upon will bring out the interesting points of the individual cases:

154 WEST 8TH ST.

TABULAR REPORT OF THE TEN CONSECUTIVE CASES OF ABDOMINAL SECTION FOR THE REMOVAL OF THE UTERINE APPENDAGES, ETC. Reported to the Ohio State Medical Society, 1889.

No.	Date.	Residence.	Medical Attendant.	Pathological State.	Remarks.	Results.	Drainage.
1	Sept. 20, 1887.	Ritche, C.H., W.Va.	Chas. Scott.	Pyosalpinx.	Was confined to bed for twenty months before operation. Cure complete.	Recovery.	Yes.
2	Nov. 16, 1887.	Piketon, O.	O. C. Andre.	Pyosalpinx.	Sick for two years. Now in perfect health.	Recovery.	Yes.
3	April 30, 1888.	Frankfort, O.	Rufus B. Hall.	Abscess of ovary.	Sick for three years. Now in perfect health.	Recovery.	Yes.
4	Sept. 5, 1888.	Sparta, O.	D. P. Bliss and B. B. Scott.	Pyosalpinx.	For eighteen months before operation patient could not sit up an hour. Emaciation extreme. Septic poisoning before operation. Died on fourth day.	Death.	Yes.
5	Nov. 3, 1888.	Bainbridge, O.	W. B. Lee.	Pyosalpinx.	Now in better health than ever before.	Recovery.	Yes.
6	Nov. 22, 1888.	Cincinnati, O.	C. R. Holmes.	Pyosalpinx.	Recovery complete.	Recovery.	Yes.
7	Dec. 27, 1888.	Minster, O.	C. L. Dine.	Pyosalpinx.	Now in good health; has no pain.	Recovery.	Yes.
8	April 13, 1889.	Covington, O.	A. F. Scofield.	Pyosalpinx.	Great sufferer for years. Large pus tubes removed.	Recovery.	Yes.
9	May 6, 1889.	Cincinnati, O.	J. S. Caldwell.	Pyosalpinx.	Now in perfect health.	Recovery.	Yes.
10	May 7, 1889,	Cincinnati, O.	C. D. Fishbune.	Pyosalpinx.	Now in perfect health.	Recovery.	Yes.

SUPPLEMENTAL REPORT TO THE PRECEDING TABLE, SHOWING ONE YEAR'S WORK OF INTRA-PELVIC SURGERY FOR THE RELIEF OF INFLAMMATORY DISEASES.
Reported to the Ohio State Medical Society, June, 1890, by Rufus B. Hall, M.D.

No.	Date.	Residence.	Medical attendant.	Pathological condition.	Remarks.	Results.	Drainage.
11	June 17, 1889.	Newport, Ky.	R. B. Hall.	Pyosalpinx.	Double pyosalpinx of nine months' duration.	Recovery.	Yes.
12	Sept. 20, 1889.	Chillicothe, O.	W. A. Hall.	Pyosalpinx.	Invalid for four years. Cure complete.	Recovery.	Yes.
13	Oct. 3, 1889.	Cincinnati, O.	R. B. Hall.	Pyosalpinx.	Patient bed-ridden for thirteen months. Now in perfect health.	Recovery.	Yes.
14	Oct. 7, 1889.	Cincinnati, O.	R. B. Hall.	Pyosalpinx.	After removal of pus tubes, ventral fixation of uterus for cure of retroversion.	Recovery.	Yes
15	Oct. 17, 1889.	Chillicothe, O.	W. A. Hall.	Pyosalpinx.	Sick for three years.	Recovery.	Yes
16	Oct. 22, 1889.	Cincinnati, O.	R. B. Hall.	Pyosalpinx.	Removal of pus tubes. Ventral fixation of uterus for cure of retroversion.	Recovery.	Yes.
17	Nov. 7, 1889.	Cincinnati, O.	C. B. Van Meter.	Pyosalpinx.	Two years before had operation on lacerated cervix which gave no relief. Now in perfect health.	Recovery.	Yes.
18	Nov. 25, 1889.	Cincinnati, O.	C. B. Van Meter.	Pyosalpinx.	Sick four years. Now well.	Recovery.	Yes.
19	Nov. 27, 1889.	Cincinnati, O.	R. B. Hall.	Pyosalpinx.	A great sufferer for fourteen months. Perfect cure.	Recovery.	Yes.
20	Jan. 6, 1890.	Cincinnati, O.	R. B. Hall.	Tubercular salpingitis.	Sick for five years. Improving rapidly. Gained eighteen pounds in weight.	Recovery.	Yes.
21	Jan. 23, 1890.	Cincinnati, O.	J. A. Murphy.	Pyosalpinx.	Sick five years. Very feeble. Improving and gaining in weight.	Recovery.	Yes.
22	Feb. 19, 1890.	Coalton, O.	Wm. Drake.	Pyosalpinx.	Sick six years. Dates abdominal pain from time of forcible dilatation of cervix three years ago.	Recovery.	Yes.
23	Mch. 15, 1890.	Dayton, Ky.	W. D. Richards.	Pyosalpinx.	Invalid for two years. Cure complete.	Recovery.	Yes.
24	Mch. 19, 1890.	Chillicothe, O.	J. W. Lash.	Abscess of ovary.	Sick five years. Bed-ridden one year. Cure complete.	Recovery.	Yes.
25	Mch. 27, 1890.	Cincinnati, O.	O. P. Holt.	Chronic salpingitis and ovaritis.	An invalid six years. Appendages removed. Cure complete.	Recovery.	Yes.
26	May 7, 1890.	Cincinnati, O.	L. A. Shepard.	Pyosalpinx.	Sick for two years.	Recovery.	Yes.
27	May 24, 1890.	Cincinnati, O.	E. S. Stevens.	Chronic salpingitis and ovaritis.	Sick for two and one-half years.	Recovery.	Yes.
28	May 27, 1890.	Vinton Co.	R. B. Hall.	Pyosalpinx.	Sick for two and one-half years.	Recovery.	Yes.

Society Notes.

THE RECOGNITION OF EYE-STRAIN BY THE GENERAL PRACTITIONER.[1]

THE above was the title of a paper by EDWARD JACKSON, M.D.:—

The attempt to give relief from the symptoms of eye-strain by a careful trial, seriatim, of one's favorite sedative, tonic, and alterative prescriptions, followed by experimentation with the formulæ of great professors found floating on the surface of medical journalism, does not usually bring much comfort to the patient or credit to the doctor. And that it is so frequently persisted in until the patient deserts his so called medical adviser, and of his own notion takes his chances with the specialist or the charlatan, seems to argue an inability to recognize the connection of this group of symptoms with their cause. The worst evil of specialism is ignorance and indifference as to other departments of medicine; one of the most aggravated manifestations of this evil is the expressed indifference of so-called "general practitioners" toward the anomalies and diseases of the eye.

From time to time efforts have been made by ophthalmologists, to secure a more general recognition of

[1] Read June 25, 1890.

eye-strain on the part of the mass of the profession; but, usually, these efforts consisted in a recommendation of some special instrument or procedure of diagnosis, as, the refraction ophthalmoscope, or the shadow-test, or a set of trial lenses, reduced in size and price to the supposed needs of the mass of the profession. If it were really necessary to apply such special means of diagnosis in order to recognize the presence of eye-strain, there would be little prospect of its early general recognition. But it is frequently recognized by the patient himself, and the ophthalmic surgeon finds in the general rational symptoms quite sufficient grounds for a provisional diagnosis; and if the mind is clear from preconceived hypotheses as to the causes of the symptoms, tending to divert attention from their real origin, there is no reason why any one respectably qualified for general practice of medicine should not be able to make a provisional diagnosis with sufficient certainty to serve for the basis of further investigation and treatment, in the great majority of cases, without resort to any special method of examination whatever. Of course, the ophthalmoscopic evidence of ametropia, when it can be obtained, is very valuable as confirming such a diagnosis; and I do not under estimate the value of the ophthalmoscope to the general practitioner, for I cannot regard any one who is unable to use the ophthalmoscope as properly qualified for general practice. But I do say that inability to measure refraction with the ophthalmoscope is no reason for failing to recognize eye-strain.

The patient suffering from eye-strain comes with a certain history and certain complaints, which, carefully considered by the light of a very moderate knowledge of the subject, clearly indicate the cause of the trouble, in the great majority of cases. The symptoms in question may be considered separately.

Impairment of vision, either quite temporary, more prolonged, or quite permanent. A very characteristic form of temporary impairment of vision is that due to sudden relaxation of the accommodation. This occurs when the ciliary muscle has long been overtaxed, and especially in the latter hours of the day, when it is nearly tired out. The patient notices that the print or other near object on which the attention is fixed suddenly becomes entirely blurred, compelling the cessation of the eye-work. After a moment, however, the power of again focusing the object returns, and work can be resumed. The patient is apt to close his eyes for an instant, and, perhaps, rub them, and on again opening finds the sight again restored. If the eye-work is continued, the failure of accommodation recurs, to again rapidly pass away; and keeping on with the eye-work, these periods of inability to see become more and more frequent, until, finally, they greatly interfere with the continuance of the work, or quite prevent it. This form of impairment affects only the vision for near work.

Another temporary impairment is that due to spasm of the accommodation; it affects distant vision only, and is noticed chiefly by those whose distant vision is otherwise pretty good. It comes on after prolonged straining of the eye, usually for near vision, and lasts until the eye has gotten well rested. It is a valuable danger-signal, and should secure cessation from the work causing it until it has given place to normal relaxation. Permanent impairment of vision is brought about when eye-strain causes myopia or decided permanent damage of the choroid and retina.

Headache and Aching of the Eyes. — Eye-strain should be the first thought suggested by any complaint of headache, for in our day and civilization it is by far the most common cause of that symptom. It enters as a factor into the causation of nearly all headaches not due to pyrexia, toxemia, or diseases of the brain or its membranes. The simple existence of headache, therefore, should suggest eye-strain; but frequently a careful inquiry as to the manner and time of occurrence of the attack, and the location of the severest pain, will be almost conclusive as to the origin of the trouble.

Often it comes on whenever the eyes are used, and is absent when they have had a proper period of rest. The occasions of most severe requirement in the direction of eye-work are the doing of anything requiring accurate near vision, taxing both the accommodation and the convergence; or traveling, shopping, attendance at public gatherings, which entail more use of the eyes than the patient is at the time conscious of, and often under unfavorable conditions.

Very often the chronological connection between the use of the eye and the occurrence of the ache, although perfectly certain and evident when once it has been observed, has never been noted by the patient until his attention has been directly called to it. Even when the headache seems constant and quite uninfluenced by variations in the amount of eye-work, it may be due wholly to eye-strain.

In hyperopia in young people the accommodation is in excessive use so long as the eyes are open and the attention fixed on any visible object; and hyperopia is the most common cause of constant headache. The writer was formerly subject to a constant headache whenever confined to the house, and regarded it as caused by breathing vitiated air, until it was quite cured by the correction of his hyperopic astigmatism. Many persons have the same idea as to the causation of the headaches they always experience when attending the theater or other place of public amusement, and which are really due to eye-strain. Others ascribe these headaches, and those experienced in traveling or shopping, to exhaustion. This is nearer the truth, only they commonly have in mind a condition of general exhaustion, whereas it is largely one of local exhaustion of the special nervous apparatus concerned in the act of seeing.

The *location of the aching* is of some significance. Generally it is frontal, often described as beginning in the eye, or just back of the eye, or through the temples. Frequently it extends to the occipital region, and may sometimes be felt principally or wholly in that region. Headache most severe in the vertex or confined to that region is probably not very common from any cause, but from eye-strain it is almost unknown. Often the headache is more severe on one side of the head than the other. Sometimes it is entirely confined to one side, but usually it is bilateral.

Those more or less regularly periodical headaches, known as nervous or sick headache, migraine, or, when confined to one side of the head, hemicrania, are in many cases set up by eye strain and relieved by its removal. Attacks of this kind are frequently ushered in by certain interference with vision and subjective sensations of light, affecting a part or the whole of the visual field, and known as ophthalmic migraine. These visual disturbances are simply a part of the general "nerve-storm," and it is not certain that they especially indicate the origin of the attacks to have been eye-strain.

Congestion, irritability, or inflammation of the eyes and their appendages should always suggest the suspicion of eye-strain. A single attack, or manifestation of this kind has no especial significance, but

repeated attacks of inflammation, or prolonged congestion, or irritability, are exceedingly suggestive of a continuing cause; and the most common of these is the one now under discussion. No case of chronic inflammation of the margins of the lids, or of recurring conjunctivitis, or repeated styes, has justice done to it until it has been carefully investigated for eye-strain. Persons at the period when they begin to feel the effects of loss of accommodation in presbyopia or absolute hyperopia, suffer from repeated attacks of conjunctivitis, which they commonly ascribe to "taking cold in the eye," but which are cut short by use of the appropriate lenses, and which, if unchecked, would tend to establish a chronic catarrhal condition, which is a chief discomfort in the lives of many elderly people.

Of course, these conditions of ocular congestion and inflammation will be recognized by the usual symptoms of redness, swelling, and itching, smarting, or burning pain. They often require especial local treatment, and will quite often be temporarily cured by this alone; but if the underlying cause is not removed, they show a strong tendency to recur indefinitely, or until the accommodation is so far lost that the temptation to strain it is removed. It should be noted that usually headache and these local inflammatory conditions are not presented by the same case. They may co-exist, but, more commonly, if one is decidedly present, the other is absent.

So far nothing has been mentioned for the diagnosis of eye-strain, but the facts ascertained by questioning the patient, and from simple inspection of the eye. If, now, the physician's office contains—what every general practitioner's office should contain—a card of test letters for accurately ascertaining the distant vision, and a card of fine print for ascertaining the near point of the eye, additional valuable evidence is easily obtainable. The trial of the distant vision will give indication of any considerable degree of myopia or astigmatism. But it must always be borne in mind that troublesome ametropia may be present without preventing perfect distant vision. The position of the near point, if farther from the patient's eye than his age would indicate, is pretty good evidence of strain of the accommodation. Evidence of strain of the external muscles of the eye, heterophoria, can be obtained by simply getting the patient to keep his eyes fixed on some object, near or distant, and covering one eye; then noting whether the covered eye deviates from its position of fixation, and especially whether it makes a quick movement to return to that position when it is uncovered.

Briefly to recapitulate, the common symptoms of eye-strains are:

Certain forms of impairment of vision.

Headache, which is to be studied with reference to the times of its occurrence and the parts of the head to which the aching is referred, with careful discrimination between the patient's facts and his theoretical explanation of them.

Chronic or repeatedly recurring congestion, or inflammation of the eye, or its appendages.

And if to these symptoms are added the results of the simple tests of near and distant vision, and evidence of tendency of the eyes to deviate from their normal position when covered, a very good basis is furnished for the probable or provisional diagnosis of eye-strain, without recourse to any special apparatus or unusual diagnostic procedure. And in view of these facts there is no justification for the general practitioner who fails to recognize most of the numerous cases of eye strain with which he is brought in contact.

Discussion.—Dr. George M. Gould: Certainly, nothing Dr. Jackson has advanced in his excellent paper calls forth controversy or criticism; but I think a word may be added as to certain other symptoms not alluded to by him, that may sometimes put the general practitioner on the track of an eye-strain reflex. When eye strain is sufficiently severe to set up a reflex neurosis, sleepiness is a common symptom brought on by persistent reading or writing. The patient cannot understand why he grows so drowsy. A more important trouble is one I at first advanced somewhat doubtfully, but now I am growing perfectly convinced is a genuine result of ametropia. I allude to troubles of appetite and digestion. Few patients with severe or long continued eye-strain that do not complain of anorexia, fickle appetite, or some dyspeptic trouble. Mothers frequently call such girls "pickers." Explain the mechanism of this reflex as we may, I am sure it is a fact, and that a malnutrition often results that may end in anæmia and many different form of nervous abnormality. I have had a large number of such patients regain long lost appetite after putting on glasses, and regain ten to twenty pounds of flesh within a month or two. Nervousness and choreic movements, even genuine choreas, are traceable sometimes to the same causes. I had one patient who wore the right shoe out in a few weeks, and who had a habit of bursting out crying or into a rage at a trifle. She had been treated for chorea for years at one of our best hospitals. All symptoms have dissappeared for two years upon correction of her hyperopic astigmatism. I could cite several other cases

I should like, also, to call attention to car sickness in connection with eye-strain. I have had eight or nine cases of this kind, and by glasses all have been relieved of the car-sickness. One case was that of a gentleman who every journey had car sickness. While he had the mydriatic in his eyes he went to Washington, and suffered no inconvenience whatever. Subsequently, after he had glasses, he made a trip to St. Paul without any of the former trouble. In the last two days I have two cases—one that of a girl who could not ride a short distance in the street cars without vomiting. I found a decided degree of hypermetropic astigmatism. With the mydriatic in her eyes she rode home without her usual trouble.

A strange thing with reference to eye-strain is, that it often exists to an exceptional degree without showing any symptoms in the eye. The patient will often say that the eyes are perfectly good and have never caused any irritation. The reflexes seem to settle in some other place. This is an interesting pathological and physiological question.

With reference to testing the eye by the general practitioner, it has struck me that a simple plan, which could be readily carried out, would be as follows: Have two test-cards, so that the patient will not learn and remember the letters. Let him first test distant vision with one of the test-cards; then let him instil homatropine. This will give perfect paralysis in three-quarters of an hour. Then retest with the other card. Then, if vision has decreased, there is eye-strain, due to astigmatism or hypermetropia. Another practical point is that, if the patient is suffering with headache, he will be relieved by the application of the mydriatic. It is to the existence of hyperopia and astigmatism that we want to know. Myopia rarely produces eye-strain.

Dr. Mary E. Allen: I would ask if, in these cases, the condition of the recti muscles has not something to do with the symptoms. In my own case, I

suffered eye-strain for a long time, and insufficiency of the recti muscles. I had one symptom which I have never seen described, and that is, a feeling as though a blow had been struck against the eye. My explanation of this is that, by a spasmodic contraction of the straight muscles, the elastic eye ball is suddenly drawn with force against the back of the orbit, giving the sensation of a blow. I had this a long time before wearing glasses, but very seldom since.

DR. JACKSON: My paper simply refers to the *recognition* of eye-strain. I purposely considered only those symptoms most generally present, and had in mind the great mass of cases, not the exceptional ones, which do, in the aggregate, constitute a very large number, but still are proportionately few. The other symptoms which have been mentioned, and many others, might be referred to as due to eye-strain, but they do not occur in the large number of cases, and can hardly be regarded as of general importance in making the probable diagnosis.

I have used the term eye-strain, not as a synonym of ametropia, because we may have ametropia without eye-strain, or eye-strain without ametropia, if requirements are put upon the eye too great for its capacity. You can have it without any ametropia or weakness of any extra-ocular muscle or group of muscles. It is to the question of eye-strain as isolated and separated from ametropia that I refer. Of course, in a very large proportion of cases, the relief of the eye-strain comes from correction of the ametropia.

In connection with that correction, I should like to say one thing with reference to a remark made by Dr. Gould—that is, if myopia were present, it need not be considered. In my experience, myopia may cause severe eye-strain. There is the strain of convergence, and any inequality between the two eyes in the amount of myopia—and myopia is usually unequal—is very likely to cause eye strain. The discovery of myopia would not, to my mind, rule out the existence of eye-strain.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

IODOL.

IN a case of chronic diarrhœa of the nervous type, of many years' standing, it was found that whenever the diarrhœa was worst fissures of the anus were present, and an appearance which I have never seen described in connection with the anus, but exactly like one which Matthews Duncan found in the vagina. There is a red spot—not an ulcer—exquisitely sensitive, which appears to consist of the vessels and nerves, the other elements of the tissues having been atrophied. Duncan found no cure for this; even when the spot was excised a similar one soon appeared in the vicinity. Temporary relief was obtained by the application of pure carbolic acid.

In the present case, iodol was applied, in an ointment of one part to sixteen. Immediate relief ensued, and, whenever any indication of a return was manifested, it was promptly checked by the iodol. The net result has been that this summer has been freer from the diarrhœa than any for a number of years.—*Waugh.*

EXOPHTHALMIC GOITRE.—The therapeutic agents that have by common consent proved the most serviceable in the management of this affection are: Galvanism, digitalis, ergot, iron, bromides, and nerve tonics, such as arsenic, phosphorus and zinc.

All writers seem to argue that, of these agents, Galvanism is the most valuable, but there is no uniformity in the directions as to the method of applying it. I have, from my experience, some reason for testifying to its efficacy, yet I think it quite important that the reverse current be used, and that it be passed as nearly as possible through the irritated nerves, with a view of producing a sedative action upon them and the nerve centre in the cord from which they originate. I have never used a stronger current than twenty volts.

As to the medical agents mentioned, they are to be employed according to the indications in each case, and their tolerance by the patient. I have found in some cases a combination of belladonna with digitalis and nux vomica, of marked benefit in controlling the rapid action of the heart, but the correction of indigestion and sleeplessness is of primary importance in conserving the patient's energy, which is, otherwise, in most cases rapidly dissipated.—Herdman, *in Med. Age.*

SCARLET FEVER, MEASLES, AND DIPHTHERIA RUNNING TOGETHER IN THE SAME INDIVIDUAL.—E. W——, aged four years and a half, was admitted into the Derbyshire General Infirmary under Dr. Greaves on March 29, 1890, suffering from scarlet fever. She had a typical rash, with sore throat and tongue. Temperature 103.2°. The fever ran an ordinary course, and on April 9th she was peeling generally, the throat being still somewhat swollen, and the glands of the neck enlarged. On April 10th, twelve days after admission, the child began to sicken again, and complained of headache; the temperature began to rise, and there was marked coryza. On the 11th she had a rigor (temperature 105.4°), and the following morning presented a well-marked measly eruption over the face, neck, and wrists.—April 13th: Rash disappearing; temperature falling; child seems better; throat still inflamed.—14th: Temperature 104°; patches of membrane seen on both tonsils.—15th: Membrane on soft palate, removal of which causes bleeding; much difficulty in deglutition, and also in respiration; symptoms of laryngitis appearing.—17th: Respiration still difficult; quantity of muco-purulent discharge from nose; throat less inflamed.—23d: Child seems better; takes nourishment well; tongue cleaner; ulcers on the tonsils, but no membrane to be seen; respiration much easier; pulse fairly good.—24th: Has had two slight attacks of syncope while sitting up to be fed; seems unable to swallow in the recumbent position.—25th; The child, after awaking from a short sleep, was rather restless, had another fainting attack, and died.

Remarks.—When the membrane first appeared on the tonsils we were doubtful as to its nature, and inclined to look upon it as merely an aphthous condition arising in the course of a specific fever; but from the way in which it spread to the larynx and nasal cavities, and the subsequent development of the general symptoms, we were induced to look upon it as a case of diphtheria, and to treat it accordingly. It is not uncommon for measles to supervene during an attack of scarlet fever, or for diphtheria to attack a patient suffering from eitner measles or scarlet fever, but the occurrence of the three together is, I think, of such rarity as to be worthy of recording.

—Taylor, in *The Lancet.*

ADDRESS ON MEDICINE BEFORE THE BRITISH MEDICAL ASSOCIATION.

LAST week we laid before our readers the Address in Surgery, delivered by Lawson Tait. The intensely practical nature of the man shows forth in every line; food for thought is to be found in every pointed sentence. The defects of our clumsily ineffective methods of preparing the student for his future work as a physician are graphically portrayed. The dolt who discourses on high science to a laborer's wife in her agony, instead of attending to her needs, can be found without crossing the Atlantic. It has even been whispered that the graduates of a certain university, that will here be nameless, talk learnedly upon the circulation of batrachians, and are not very skilful in the treatment of scabies. But the part of Mr. Tait's address which gives most pleasure is that in which he speaks so courteously of Sir Spencer Wells. As Mr. Tait grows older he loses something of the acerbity of his earlier years; he can recognize the good that has resulted from the labors of his enemies; and, by doing so, he lifts himself to a higher place in the estimation of his friends. There is also a noticeable absence of rancor in his remarks upon Apostoli and his methods. Altogether, it has been long since we have perused an address with as much pleasure as that of Mr. Tait.

We regret that our space is too limited to admit of the reproduction of the other addresses. In that upon medicine, Foster dwelt upon the achievements of the experimental method in bacteriology and organic chemistry. The story of the microscope has nowhere been told better. Schwann connected fermentation with yeast-cell multiplication; the association of micro-organisms with putrefaction came next; the doctrine of a living cause of specific disease received fresh support, and Pasteur's vitalistic theory of fermentation led Lister to his triumphs. Nægeli's experiments dislodged the great chemical champion, Liebig, from a series of positions he had defended with the greatest skill. Half a century before, Henle had foreshadowed the connection of infective diseases with micro-organisms; and, in 1849, Budd declared his belief that cholera and typhoid fever depended on living organisms. Like many an ardent student, he longed for and foresaw the day when, in connection with zymotic diseases, the initial phenomenon of the morbid series would be isolated and defined. Pollender's discovery of the anthrax bacillus, and its study by Davaine, etc., opened the new field of study. New methods of investigation, new arts of studying the life history and morphology of bacteria, by cultivating them in nutrient media, were devised; and inoculation revealed new and startling facts as to the virulence of micro-organisms and the modifications by which they are rendered protective. Pasteur, at last, found parallels to Jenner's discovery, in chicken-cholera, anthrax, and hydrophobia. There is a law, widely applicable to pathogenic organisms, that their own products become in time destructive to themselves. The saturation of the system with the products of the microbe stops its multiplication and renders it inert. Hence, inoculations of the product tend to prevent the development in the body of the original microbe. Looking closely at this theory, we get a side-light of startling suggestiveness as to the true foundation of the old idea of the *vis medicatrix naturæ;* as in the modified intensity of virus produced by culture we see the origin of the theory of the change in the type of disease.

The chemists are now at work upon their part of the investigation; and have already isolated virulent compounds from putrefactive substances. In some septic diseases, toxic products are probably generated by the metabolism between the bacteria and the bodily tissues. Some researches indicate that a bacillus always produces the same poison, and that this causes the graver symptoms, as in diphtheria. The position now reached is, that in some diseases, as anthrax and relapsing fever, we know a specific micro-organism to be the contagium; in a second group, as tubercle and cholera, the evidence is nearly complete; in a third, the matter is still *sub judice*.

The lesson that these results teach us is that experiment and comparison have vastly changed our notions of disease, by substituting actual demonstrations of morbid processes for vague speculations. We no longer refer an epidemic to the anger of the gods, or to some intangible emanation, but we find its cause with the microscope and the culture flask. We identify and isolate the microbe, and that done, or even before it is done, we learn by experiments to modify and master its effects. "Shutting out fear with all the strength of hope," experimental medicine aims at discovering and controlling the starting-point of each infectious malady. In every instance in which that is accomplished, the arts of prevention and cure hasten forward with hurrying feet, but with by no means equal steps. Bacteriology gives, in the first place, the strongest impulse to preventive medicine, by defining the causes, and in many cases giving the power to control and modify at will the initial phenomena of each morbid series. With these revelations of the nature of pathological processes; with these disclosures of the causes of disease; with these demonstrations of what I may call the mechanism of maladies, is it any wonder that the attitude of the profession to disease is vastly changed?

The mystery that awed and paralyzed us in so many cases thirty years ago, has yielded its secret to patient study, and, confident in the new knowledge, we hail

> The teeming future
> Glorious with visions of a full success.

These revelations of the causes of illness favor the success of collective efforts at prevention; and, hence, the State has more willingly legislated for this object. While medicine was a slave to theology or metaphysics, little progress could be made. The shafts of Apollo formed as hopeless an explanation of an epidemic as the possession by evil spirits. Such ideas gave nothing definite to aim at. The identification of the contagia, their modes of communication, and the means of checking their spread, allow the formulation of rules for collective action against the common foe.

The speaker went on to sketch the progress of legislative sanitation in Great Britain during the reign of the present Queen. He paid a pleasing tribute to Birmingham, noting the title of "the best-governed city in the world," applied to it by a recent American visitor, and closed with the following, which smacks of Bellamy:

Go and see, I ask you, how Birmingham takes care of its fifteen hundred sick poor, and you will, I am sure, appreciate the wise benevolence that has raised this great medical monument of Christian charity. There is, to my mind, only one defect: every one who is admitted is forced to become a pauper. I hope one day sickness and suffering will be sufficient passport, and that the benevolence which proffers the relief will not mar the sweetness of the gift by a condition which embitters its receipt. When that day comes, and the collective provision for the sick is made a public duty, many hospital abuses will be cured by the municipalization of our charities. The isolation of infectious cases has already been put upon the rates without entailing pauperism, and our City Hospital contains some four hundred beds. Thus these two rate-aided hospitals receive some two thousand patients, or between three and four times as many as are maintained in voluntary hospitals. In London a similar condition exists, for there nearly two-thirds of the eighteen thousand in-patients are supported from public funds.

Some of you may say I began this address with philosophy and I end it at a workhouse—a goal which philosophy sometimes attains. I accept the criticism. It states a truth and conveys a lesson. It is that lesson which I wish to impress upon my professional brethren—the immeasurable importance of even their highest scientific work to the well-being of the poor, and through that to the stability and prosperity of the State. We have in our ranks some four thousand five hundred poor-law medical officers, who are the daily bearers of succor to suffering thousands, and in many cases the only visible link between the powerful State and the homeless and hopeless poor. In the daily work of these four thousand five hundred doctors there reside greater potentialities for social progress than in any other class. To them is given the highest function committed to us by the Highest—the care of the suffering poor—and in the daily discharge of that holy task, the vast hecatomb of human misery that civilization piles up may be diminished and prevented. If it is not so prevented, decay will come upon us as a nation; for never yet have strength and stability been found in hoarded wealth, but only in the content and comfort of the poorest classes of the population. I want every parish surgeon, every practitioner among the poor—and thank God we all have poor patients—and every medical officer of health, to realize the nobility of the service he gives the State; and one day, I hope no distant day, the State will awaken to the value of such service, and recognize in the trusty dispenser of a nation's charity, or the wise saviour of a city's health, servants of the State more worthy of its honors than the successful soldier, or the astute diplomatist.

But come this higher hierarchy of worldly honor soon or late, to men who do their duty in our ranks, there will come one day the grandest words of welcome and reward, "Well done, thou good and faithful servant; enter thou into the joy of thy Lord."

Annotations.

MATÈ.

CHARLES, in the *British Medical Journal*, contributes the results of an investigation of matè, or Paraguay tea. The proportion of caffein in this he found to be 0.79 per cent., as compared with 1.2 per cent. in coffee and 3.1 in tea. The per centage of tannic acid was 21.9; 5.8; and 22.7 respectively. Matè has the effect of increasing peristalsis; it also acts as a diuretic; but neither action is sufficient to interfere with its use by persons in health. In two cases where Charles induced old ladies to substitute matè for tea the effect was beneficial; their headaches ceased, and after a year they were quite contented with their substitute for the "cup that cheers." There are many cases in which neither tea, coffee nor cocoa are advisable and agreeable also; and it would seem as if there is room for the introduction of matè as a popular beverage in this country.

COMMENTING on the interest shown by the electric light people in condemning execution by electricity, the *Scientific American* says:

"We have only to say, if they are not satisfied with the electrical apparatus used at Auburn, if, as they claim, it is not effective, then let us employ the deadly devices which the complainants themselves use, own, and control, with which they fill our streets and slay our innocent citizens. Let them bring the culprit to our city prison, place him on a conducting floor, introduce one of their street light wires, and with it, at the moment of execution, touch the hands of the prisoner. It will extinguish life instantly. It has rarely been known to fail."

We fear that in their eagerness to discredit electrical execution these gentlemen are proving too much. If Kemmler's death was so frightfully painful, if he were "tortured to death," this furnishes an excellent reason for recalling the charters of the electric light

companies, and compelling them to suspend operations until they can devise methods by which the public will be protected. Sympathy with the brutal murderer is all very well, but how about the innocent victim who happens to touch the tip of a telephone wire, that has somewhere crossed an electric light wire, and is "pounded to death?" Be careful, gentlemen, or you will be "hoist by your own petard."

HEMIPLEGIC EPILEPSY.

THE difficulties that still beset the path of cerebral surgery are exemplified by a case related by Abbe, before the New York Surgical Society (*N. Y. Med. Jour.*) The patient, a man aged forty-four, had a mitral murmur; no paralyses, no deviation of tongue, no anesthesia, pupils reacted to light, knee-jerk absent; the other reflexes present, the plantar exaggerated. There was a purulent discharge from the left ear, with perforation of the drum. Skin dry, tongue brown but moist; pulse 80, temperature normal. The man was somnolent. An hour after admission he had convulsive movements of the right side, beginning in the foot. Next morning he had a limp. After breakfast another convulsion of the right leg, followed by transient paresis and hyperesthesia. The urine was acid, s. g. 1,042, with no albumen or casts, but 32 grains of sugar to the ounce. During the following week the urine increased from 40 ounces to 86; several attacks of anesthesia of the right arm and leg occurred daily, with loss of power. He could stand but could not walk. No optic symptoms. Hesitancy in speech and difficulty in pronunciation. Mind dull, memory good. The convulsions recurred several times daily, with more pronounced aphasia, and extended to the face (right side). Temperature 101° F., and evidences of mastoid suppuration. It was thought possible that there might be pressure upon the centers for the leg, arm, face and for speech, from perforation and extension of the suppuration. The mastoid was opened, and a loose requestrum removed. The convulsive twitching continued, and on the third day following, the indication of irritation of the cortex being pronounced, with slow pulse, wholly localized convulsions and more complete aphasia, it was decided to trephine in front of the lower end of the Rolandic fissure. No gross lesions were found either at this time, or at the autopsy, five days later.

The conclusion was that this train of remarkably delusive symptoms resulted from the diabetic toxemia; the mastoiditis determining the irritation of the left convolutions.

Letters to the Editor.

ELECTRIC SHOCK.

WM. R., male, white, aged twenty-one years; an employé of the U. S. Electric Co.; while fixing the carbons received a shock of 2,000 volts; the current entering through a hole in his rubber glove at the second phalanx of the middle finger of the right hand and passing out through the left forearm, charring the flesh at both places. The current lasted only three or four seconds. In describing the sensation he said there was no pain, but he felt as if he were violently shaken, and then lost consciousness. He was unconscious about five or six minutes. He then walked to the Emergency Hospital, where the burns were dressed. Said he felt all right, and was going to work the rest of the night. For several days he felt sore all over his body, as if he had been taking violent muscular exercises, but not enough to stop him from work.

R. M. ELLYSON, M.D.,
Resident Physician.

EMERGENCY HOSPITAL, WASHINGTON, D. C.

THE CATSKILLS.

ALTHOUGH I am up here in the clouds I do not forget my earthly friends. It seems queer how people seek for health, under the earth or in the clouds. I was led to this thought by reflecting on the memory of a dark, gloomy abode in the Mammoth Cave, which I was assured by my guide had been occupied by a number of people for months in the hope of a cure for phthisis. Up here the sight of the heavens, apparently so near, the beautiful valley of the Hudson extending in all its grandeur about three thousand feet below, is enough to inspire feelings of elation as we drink in the pure air untainted with the vile odors of the swill cart, odorless excavators and the host of air polluters of the city. One thing has astonished me. The thought of how many cross the ocean in hunt of grand scenery, when here, only two hundred miles from Philadelphia, a few hours' ride, they can enjoy the grandest views of mountains, valleys, water falls, ravines, etc., and drives or rambles o'er hill and dale, all conducing to health and happiness. Or, if desired, rest, while drinking in the wonderful scenery lying at their feet seated on the grand porch of the hotel. In all my travels, I have nowhere met with hotel life more comfortable, or scenery to surpass the outlook from every portion of the mountain upon which this hotel is built.

WM. B. ATKINSON, M.D.

HOTEL KAATERSKILL, N. Y.

Paris Letter.

JEALOUS INSANITY.

PROF. BALL, who holds the chair of Mental Medicine at the Faculty of Paris, gives some interesting clinics at the St. Anne public asylum.

Dr. Ball is of English descent, although of French birth. It is rather curious to note the extraction of some of the greatest men France has had. Notwithstanding that the French are strongly prejudiced in favor of Frenchmen, still quite a number of men of foreign parentage reach the best possible places. In the Paris Faculty of Medicine there are several instances besides that of Prof. Ball. The late lamented Prof. Damaschino and the present Prof. Panas are of Greek extraction. But, to return to our subject—

It is usual to look upon jealousy as a partial and harmless form of delirium; but it is, nevertheless, in certain forms, a fixed pathological state, which should be known and studied by all physicians who wish to understand mental medical facts. The insanity that it sometimes leads to cannot be taken for the more or less natural exaggeration of a natural instinct.

Dr. Ball, first of all, attempts to define jealousy. He says it is a "general inclination (like envy, and founded, like it, also on egotism) that makes certain persons demand the first place in everything, and get angry at any preference shown to others." This may be shown for various matters; but the usual case, and the one studied here, is jealousy through love. This is generally thought to carry its justifi-

cation in itself, because it is supposed to be shown by an excess of tender sentiment and love.

This is a profound error; although a general belief among the public, and accounting for the verdict of acquittal so often given by juries in such cases. But, in reality, real jealousy is a sentiment that is profoundly egotistical; the jealous person is much more hurt in his or her self-appreciation than in his or her affection. The true type of jealousy was immortalized by Beaumarchais, in his character of the Count Almaviva in the "Barber of Sevilla," who makes love to all the women he meets, but gets furiously jealous if any one speaks to his Rosine. Many jealous insane persons have been known to kill the object of their so-called affections rather than that the preference should belong to a rival.

Dr. Ball presented two patients to show his ideas. The first was a woman of forty-six, who was rather good-looking: but, from her age, one would have thought had passed the age of jealous insanity; but it may well be that it was just that that brought it about. Up to the menopause, which had come on in October last, she was reasonable, or at least had contained within reasonable limits her malady. She had been a cook in the best families, while her husband had been a valet; they both ate and drank well, and she was somewhat alcoholic; added to this, the fact that her husband had been foolish enough to relate to her some of his youthful follies, and also some of those of his master's. This put the woman into the first stage of excitation, and led to her following her husband wherever he went. She fell into the grave mental state called by Prof. Ball "obsession," which gets such a mastery over jealous women that all their thoughts and acts are directed to a single object. She harassed the husband so much that he at last killed himself. And just here is an important symptom. Notwithstanding that she says she loved her husband, she don't really regret him, as she is gay and quite indifferent about his death. This sort of indifference is quite characteristic of insane patients of all kinds; anything that is outside of the fixed idea on which they are deranged does not affect them. Her only idea at present is that her husband can no longer be unfaithful to her; so much is this so that she will soon be cured; above all, as she cannot get alcohol here.

This case of jealous insanity was, as we have said, of alcoholic origin. Jealousy, indeed, is only a form of delirium.

The second case is quite different. It is a woman who does not care for her husband at all, and who only sees herself in the world. She was a spoiled child, allowed by her parents everything. She soon became accustomed to see only her own ideas in everything.

After her marriage, to a good husband, she soon made him suffer, as during her second pregnancy she was taken with jealous insanity. Her husband was employed in a government office, but she could not remain at home and take care of her daughter, but must run constantly after him, just as she was, without a care about her dress; with her old kitchen apron on. She would remain for hours outside his office. When he would come out she would scream out that he had been with the female porter of the house, that he disgraced her, etc., etc.

After many scenes of this kind the husband saw a doctor, and she was finally brought here, where her bad character makes her jealous of everybody. She cries, and beats the other poor, simple idiots, and will throw handfuls of pepper into their soup. She says she hears voices, who tell her that her husband is unfaithful with all sorts of impossible people—the charcoal woman, etc. She constantly refuses to eat, to attract pity from the attendants and public; says she will not bathe, as the baths are used by dirty people. She is, in fact, completely insane. This, then, is a complete and incurable form of jealous insanity.

Jealousy, then, will produce crime, murder, suicides, and serious persecution. The journals are often full of crimes through its influence.

M. Moreau, of Tours, proposes this classification of such cases:

Class 1.	Slight jealous insanity	—	Spiteful, worry, making scenes.
" 2.	" "	"	—Rows, violence, menace of homicide, but not carried out.
" 3.	Violent "	"	—Murder.
" 4.	" "	"	—Suicide.
" 5.	" "	"	—Murder and suicide.

Prof. Ball, however, thinks the great point is whether the jealous patient is mad or not, and gives two classes:

1. Simple jealousy.
2. Jealous insanity, with or without hallucinations.

Mothers have been known to kill their children and then themselves under jealous insanity. Is this the first or second class? It is sometimes difficult to say; but what is certain is that such persons are a public danger, and they should be sequestrated. To kill a husband through jealous passion can sometimes be explained by simple jealousy; but to kill her own children, never! It then becomes madness. This has been known since the ancients. Euripides tells of the jealous fury of Medea, who killed her children when she was abandoned by Jason. But the moment maternal sentiment gives way to jealousy, there is evidently a real mental malady and madness. The causes of this disease are various—heredity is an important one, education is another; a single child, also, as they are so often spoiled. Accustomed to have their every wish gratified, they are apt to consider themselves the pivot on which the world turns. Sex is important, woman being more jealous than man. But some men are jealous tyrants. Certain accidents, wounds of the head, etc., as well as diseases, such as serious fevers, can provoke this state; but above all alcoholism is the most frequent cause, with the menopause.

Jealous insanity is, therefore, a real malady, and needs our intervention. It can be cured sometimes, as our first evil shows, and the best means is to calm them by repose and sequestration. They must be taken away from their friends and their false impulses broken; and, like all undisciplined people, they must be taught reason. In this way the army is a good place to send young men. To know that one is dominated by the will of others is often a good thing, so that an asylum has here its best uses. Purgatives are important. It is curious that constipation has a bad influence over our thoughts; besides this tonics, baths, opium and bromides calm, in fact, the intensity of the attack, and reasonable beings can be returned to society who otherwise may cause difficulties that may leave serious and important consequences, both in a social and medico legal point of view.

NEW TREATMENT FOR CHOLERA.

The presence of this disease on the Spanish frontier, and in other parts of the world, with its difficult treatment, induces us to mention the fact that M.

Roux has communicated to the Societe des Sciences Medicale de Lyon, some studies he has made on Koch's bacillus, with different culture liquids. It seems that one of these last fluids was made from the residue of germinated barley, and that it is impossible to cultivate the cholera micro-organism in soups, made of the refuse of malt houses in 5 to 10 per cent. strength. It would seem, then, that a decoction of this stuff ought to be a good cholera medicine, and it will be a new use for it, instead of giving it to the animals to fatten them. The question will be to make it palatable or to inject it into the rectum. As most of the antiseptics that kill the cholera microbe are dangerous, it is certainly a happy idea to find some substance that will destroy the bacillus and not the patient, so that the above soup, even if nasty, cannot be harmful, and our druggists had better study the best means to get it into the bowels in sufficient quantity to overcome the cholera micro organism, if it is the real cause of the disease, which may be among us this year.

ANILINE COLORS IN THERAPEUTICS.

These pretty colors, which have been so long used in bacteriological work, have just now taken a new turn, and seem to be useful in the drugging branch of medicine. In place of showing up the microbes under the microscope, it is now hoped that they will arrest their development.

This idea *a priori* seems natural enough. Kriemarski spoke of it first in tuberculosis, and Prof. Stilling, of Strasburg, gives some results of its use that are at least encouraging. Quite a number of German authors have written on the subject, some quite in favor, while others still sceptical. The colors used have been the methyl violet and auramine, or yellow, which have been first carefully cleansed of carbolic acid, and arsenic. These colors thus prepared, have been called *Pyoctanine* (to destroy pus), but the name is not yet, at least, justified.

Injections made into animals, by many authors, prove that these colors are not toxic, that they possess a strong diffusive power; do not coagulate albuminates, and their antiseptic power is almost equal to corrosive sublimate. These colors are employed to cover wounds, ulcers, etc., until they crust over, and this is allowed to remain until it falls. They are also made into pencils for use in eye troubles, as well as in pomades. In solution they should be carefully filtered and kept from the light. The strength is from 1 to 10 per cent. Stilling, Peterson, and other eye surgeons are using these preparations with success. The same may be said of the nose and throat specialists. Many others are making subcutaneous injections in various painful rheumatic and other affections, so that the use of these substances is pretty certain to extend.

THE NEW FRENCH MEDICAL BILL.

Whatever may be said against this new bill it cannot be objected that it has been hurried through Parliament. The question has been studied for years, and more than a year has elapsed since it was brought before the *Chambre des Deputies* (Congress). The Minister of Public Instruction has now submitted a revised bill to the committee appointed to study the subject, and in its present matured form it will most likely soon become law.

As far as it regulates the position of foreign practitioners in France, there will not be any change from the practice of the past ten years. The clause in regard to it will read about like this: "All foreign medical doctors, who wish to practice in France, must pass an examination before a public jury of professors at one of the French medical faculties, and obtain the degree of M.D." There will then follow a clause saying that the faculty of medicine can throw off a certain number of the eleven examinations *when the candidate presents diplomas of value*. We have before stated that the French faculties have a full list of all the foreign faculties who give diplomas of A.M. M.D., etc., etc., and they know just what the equivalent value of each is to theirs. For instance, as regards American faculties, the three-year school doctor would get more than the two, etc. We might say, at the risk of repeating ourselves, that as regards American medical diplomas in general, they are not often accepted for more than one (the first) out of the eleven examinations in medicine in France. One of your new professors (at the Medico Chirurgical), Dr. Laplace, can confirm this, and tell of having to pass *ten* examinations to get his M.D. Panas and many others have had to pass all the examinations. As is already well known the French school requires of its students a Master of Arts degree before the student enters for his four years medical course. This degree, called the *baccalaureate*, is about to be modified.

While the legal course is four years at the French medical faculties, there are very few students who pass their examinations in five years, and many take six and seven years. One of the reasons for this, is that the faculty of Paris, for instance, does not go over the subject matter of the examinations yearly as is done in America. Many of the professors take as much as seven years to go over, in lectures, all the subjects they teach. We remember Prof. Sappey (when he was Professor of Anatomy) taking one whole year to lecture on the lymphatic system. This leads the students to stick to their books and hospital work, and coach up the examinations in their last year, which often gets them *adjourned* when they come up, or referred to their studies for three months at a time, and delays their final passing.

This state of things has led to quite a large section of the French hospital doctors making an agitation for the creation of a new medical school in Paris, to be called the "Hospitals' Medical School," leaving the present medical faculty to be a sort of high school (for examinations, etc). The large number of Paris hospitals, with their excellent staff of doctors (who are quite willing to teach) would make a fine *practical* school of medicine, and draw many students from Vienna. At present, while entrance for purposes of study is free to all in the Paris hospitals, the teaching is not carried out in full. Many hospital doctors give free clinics, but no organized courses are given in the *public* hospitals. Still plenty of private lessons are given in clinics, etc.

FOREIGN MEDICAL STUDENTS IN FRANCE.

The Paris medical papers are giving the number of medical students in France; and, as these statistics will be copied into our American medical journals, it may be well for me to say that, translated exactly, it will lead to errors as regards the number of American students, which is put down as *161!* In Europe, all the peoples of both the United States and South America—taking in Mexico, Brazil, and all the South American States—are known as *Americans*. The real number of United States of America medical students in France is not over a dozen, perhaps 6 in Paris, and the rest at Nancy, Bordeaux, and the other faculties. The following is a list of all the foreign medical students in all the French faculties: Full

number, 907; of which 9 are Germans; 56 English; about 12 United States of America; 150 other Americans; 7 Austrians; 9 Belgians; 22 Bulgarians; 37 Spanish; 41 Greeks; 13 Italians; 18 Portuguese; 87 Roumanians; 268 Russians; 39 Servians; 19 Egyptians; and the other countries give one or two each only. Of course, this does not include the thousands of French students. THOMAS LINN, M.D.

PARIS, August, 1890.

Book Notices.

ESSENTIALS OF ANATOMY AND MANUAL OF PRACTICAL DISSECTION, together with the ANATOMY OF THE VISCERA. Prepared especially for students in medicine. By CHARLES B. NANCREDE, M.D. Third edition, revised and enlarged, with thirty handsome full-page lithographic plates, in colors, and one hundred and eighty fine wood cuts. Philadelphia: W. B. Saunders, 913 Walnut St., 1890.

This is a good dissector's manual; with nice, clear type, and handsome cuts. The colored plates are especially commendable.

ESSENTIALS OF REFRACTION AND THE DISEASES OF THE EYE. By EDWARD JACKSON, A.M., M.D., and ESSENTIALS OF DISEASES OF THE NOSE AND THROAT. By E. BALDWIN GLEASON, S.B., M.D With one hundred and eighteen illustrations. W. B. Saunders, 913 Walnut St., Philadelphia.

A very good question-book for students preparing for examinations. The object being simply to refresh the memory upon subjects already studied in the systematic works, this volume accomplishes it very well.

A COMPEND OF EQUINE ANATOMY AND PHYSIOLOGY. By W. R. BALLOU, M.D. With twenty-nine graphic illustrations. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut St.

Certainly there are few physicians who are not sufficiently interested in the horse, to make them desirous of knowing something of the anatomy and physiology of the animal. To those who lack time and inclination to attack the larger works like Chauveau, this compend affords what may be called a "long-felt want."

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. Vol. VII, No. 1. July, 1890.

Contents: Stricture of the Rectum, by Chas. B. Kelsey, M.D.; Influence of Heredity on Alcoholism, by Dr. Paul Sollier, Paris; Rabies, by Louis Pasteur, Paris; Colotomy, by Thos. Bryant, F.R.C.S.; Massage of the Abdomen, by Dr. Rubens Hirschberg.

Pamphlets.

Scheme of the Antiseptic Method of Wound Treatment. By Dr. Albert Hoffa. Translated from the German, with additions, by special permission of the author, by Aug. Schachner, M.D., Ph.G., Louisville, Ky.

In this the entire antiseptic method is presented in the form of a chart, which can be hung up in the office. It is very ingenious, and conveys a great deal of information in a way to impress it upon the memory. The price is not given.

The New Treatment of Peritonitis. By Emory Lanphear, M.D. Reprint from *Kansas City Medical Index*.

The Present Status of the Operations of Intestinal Anastomosis and Enterorrhaphy, and the Comparative Merits of the Various "Aids" that have been Recently Suggested in the Performance of these Operations. By Rudolph Matas, M.D. Reprinted from the *New Orleans Medical and Surgical Journal*.

We are sorry to see that Dr. Matas, like many others, persists in crediting Dr. Davis' paper to the wrong journal. An abstract was published elsewhere, but the paper in full appeared only in the TIMES AND REGISTER, to which it was furnished by the author.

A Report of Six Cases of Vaginal Hysterectomy. By E. E. Montgomery, M.D. Reprinted from the Transactions of the Philadelphia County Medical Society, May, 1890.

ELECTRICITY IN GYNECOLOGY: THE GALVANIC APPARATUS. By C. N. SMITH, M.D., Toledo, Ohio. Reprinted from the Toledo *Medical and Surgical Reporter*.

CŒLIOTOMY. By R. P. HARRIS, A.M., M.D., Philadelphia, 1890.

Dr. Harris argues that cœliotomy and not laparotomy, is the proper Greek synonyme of abdominal section.

DOSIMETRY IN COLORADO, AND REFORMATION IN THE PRACTICE OF MEDICINE BY THE DOSIMETRIC METHOD. By J. E. MACNEILL, M.D., Denver, Colorado.

Somewhat sophomoric attempts at glorifying the dosimetric system, written for lay circulation rather than for the profession. One would think that the dosimetric system is better fitted for the "elegant and effete East," than for the vigorous young giant of the West, the Centennial State, (we beg the author's pardon if we have plagiarized his style), but this does not seem to be the case. When the dosimetric boomlet was yet in the dewy freshness of its roseate dawn, we betook us to the great metropolis of the East and bought some dollars' worth of granules from M. Fougera. The cute little vials captivated the ladies' eyes, but we quite failed to find the long-looked-for elixir in them. The granules of Chanteaud behaved themselves very much like those of Schieffelin, Wyeth and McKesson; and we were unable to see any advantage in substituting the French make, except to Chanteaud. The accuracy of medication can be secured quite as well by the use of any other manufacturer's goods; and the pushing of Chanteaud's is the only *raison d'etre* of dosimetry.

The Medical Digest.

KUMS recommends hypodermic injections of Hoffmann's anodyne for the relief of neuralgia.

AGARICIN, in pills made by McKesson and Robbins, has not proved of any value whatever in a case of night sweats of phthisis.

AMYLENE HYDRATE in half an hour shows its hypnotic effect, which lasts eight hours, and leaves the patient refreshed.—*Merck's Bulletin.*

BISMUTH has been found a useful remedy in gleet, but Bennett (*Amer. Pract. and News*) reports a case in which bismuth collected in the urethra until it formed an obstruction to the passage of urine.

TYPHOID FEVER AND VENEREAL DISEASES.—Isham, in the *Lancet-Clinic*, mentions four cases in which the supervention of typhoid fever apparently cured pre-existing gonorrhœa. The same good result was noticed in two cases of syphilis.

FAULKNER reports the case of a young woman who received a burn on the face, blistering the skin and leaving a scar. This was followed by pigmentation and a luxuriant growth of hair.

—*N. Y. Med. Journal.*

In speaking of the use of pilocarpine in puerperal convulsions, Edwards (*Va. Med. Monthly*) called attention to the danger from the accumulation of fluid in the bronchial tubes. If the bronchorrhœal action of the drug were great, the patient might drown in a convulsion.

Hepatic Abscess.—Hache enumerates the following symptoms: Hepatic pain fixed, limited, aggravated by pressure; widening of one or two intercostal spaces over the abscess; fluctuation, if superficial. The exploring needle is a harmless means of completing the diagnosis.

Paroxysmal, Spasmodic Indigestion is the name given by Upshur (*Va. Med Monthly*) to a case of pain about the pylorus, running down to the right along the ribs. This recurred about every ten days. It was relieved by nitro-glycerin in doses of gr. $\frac{1}{50}$; followed by tonics, light diet, etc.

Agaricic acid is reported by Kahler (*Merck's Bulletin*) as quite useful in relieving night sweats of phthisis. He gave $\frac{3}{4}$ to $1\frac{1}{2}$ grain. There is some difference of opinion as to whether the dose should be taken at once or divided. The antihydrotic effect sets in after several hours, and lasts about twenty-four hours.

Adonidin.—Oliveri reports good results from this in aortic and mitral insufficiency. He used the pure glucoside and the tannate, in doses of $\frac{1}{6}$ to $\frac{9}{10}$ grain, with chloroform water and ammonium carbonate, four times daily. These doses are questioned by *Merck's Bulletin*, as being nine times as large as those recommended.

Diabetes Insipidus.—Lindsay reported a case (*Brit. Med. Journal*) in which codeine and valerianate of zinc failed. Extract of valerian was then given in 5-grain doses, three times daily; and in a week the daily excretion of urine fell from 350 ounces to 50 ounces, and remained thenceforward at, or near, the normal point.

Phenyl-acetic and beta-phenyl-propionic acids are recommended as aiding the appetite and increasing digestion in phthisical cases; the former in the tubercular and the latter in pneumonic cases. Dose, ten to twenty drops of a concentrated alcoholic solution (1 to 6) in an ounce of water, thrice daily.

—*Merck's Bulletin.*

Mercury Hypodermically.—

℞.—Hydrargyri salicylat.....gr. xxiv to xxxvj
Mucil. acaciæ ..... ♏x
Aquæ dest.....℥j
M. ft. emuls.

The local reaction from this is said by Szadek to be very slight.—*Prov. Med. Jour.*

In Dysmenorrhœa of nearly all the common forms, particularly the congestive type from which girls and young women so frequently suffer, antipyrin is the best means of relief I have ever employed. I commonly prescribe a powder of fifteen grains of antipyrin with ⅙ grain of morphine, one powder often sufficing for each menstrual epoch. Given as soon as pain is felt it ordinarily quite averts the customary suffering and the period is passed in comfort.—Reding, in *Kansas Med. Journal.*

For Hæmoptysis.—

℞.—Tinct. digitalis gtt. xx. Every four hours.
Apply blister over the second right intercostal space, at the margin of the sternum. Order dry diet, ice, and no stimulants. Keep bowels open by means of glycerine enemata.

—*Waugh.*

For Infantile Pneumonia.—

℞.—Quininæ bisulph..... ℈j.
Ol. theobromæ..... ℥j.
M.—et in supposit. No. iv, div.
S. One every eight hours. Also, paint the back of chest with iodine and envelop in flaxseed jacket. Internally, give digitalis or ergot, in small doses.

—*Waugh.*

For Cholera Morbus.—

℞.—Tinct. capsici..... ℥ij.
Ol. cajuputi..... ℥ij.
Chloroformi..... ℥j.
Æther. fort..... q. s. ad. f℥ij
M.—S. ℥j to be taken, without water, every half hour till relieved.

—*Waugh.*

For Summer Diarrhœa in Children.—

℞.—Zinci sulphocarbolat..... gr. ss.
Bismuth subnit..... gr. ij.
Codeinæ ..... gr. $\frac{1}{24}$.
M.—Fiat tablet, No. j.
S. To be taken every one to three hours.

For children after the second year.—*Waugh.*

For Summer Diarrhœa in Adults.—

℞.—Tinct. hydrastis ..... ℥j.
Syr. rhei. aromat. ..... ℥v.
Potass. carb. *vel* nitrat..... ℥ss.
M.—S. ℥ss every four hours.

—*Waugh.*

For Amenorrhœa.—

℞.—Hydrargyri bichlorid..... gr. iv.
Sodii arseniatis..... gr. ijss.
Strychninæ sulphat..... gr. ss.
Potassii carb. pur.,
Ferri sulphat. exsic. .....āā gr. lx.
M.—et div. in pil. No. lx.
S. One pill after each meal.

—Winton, *Occid. Med. Times.*

From an examination of the urine of patients with typhoid fever and with scarlet fever, Luff (*Brit. Med. Jour.*) concludes that in each of these diseases a hitherto undiscovered ptomaine can be found in the urine during the febrile period, but disappears during convalescence. No ptomaine could be found in typhoid stools when fresh, though after forty-eight hours' standing one was apparently developed. The significance of these bodies has not yet been determined.

For Epilepsy:—

℞.—Rubidium ammonium bromide.... ℥jss.
Distilled water..... ℥iij. ℥ij.
Syrup of lemon ..... ℥v.
M.—S. Dose, ℥ss every two to four hours.

Merck's Bulletin also mentions a bromide of cæsium, rubidium and ammonium, a triple salt, as probably still more serviceable; but it is unlikely that these expensive salts will prove more effectual than the ordinary bromides, unless, perhaps, in some exceptional cases where the latter cannot be given.

THE SILVER LINES OF PREGNANCY.—Langdon thus summarizes a short paper in the *Cincinnati Lancet Clinic:*

1. The abdominal lesions known as "*striæ albicantes*," or "silver lines" of pregnancy (and other abdominal distentions) are a true deformity, due to over-stretching of an abnormally nourished skin.

2. Their prevention may be accomplished by daily inunctions of olive oil, followed by gentle hand friction for about ten minutes; the treatment should begin at or before the fourth month, bearing in mind that prevention, not cure, is the object sought.

3. Corsets, constrictions and suspension of clothing from waist bands are to be avoided entirely—at least after the third month of pregnancy.

To paraphrase the old adage—the lines are "silver," their absence golden. Another desirable object attained by the treatment is relief from the aches and shooting pains often complained of, which are largely due to the irregular stretching and compression of the nerves of the abdominal parietes.

DIAGNOSTIC TABLES.—

PROSTATITIS.	CYSTITIS.
1. Not a common disease.	1. A common disease.
2. Pain chiefly restricted to perineum and anus, and accompanied by fullness.	2. Not so limited and little if any perineal or rectal fullness.
3. Pain violent and throbbing.	3. Pain is not throbbing.
4. Stream of urine diminished in size.	4. Stream of urine may be normal in size.
5. Pain aggravated during defecation.	5. Not necessarily so.
6. Retention of urine probable.	6. Improbable.
7. Digital examination of the rectum reveals marked swelling and tenderness of the prostate.	7. No enlargement, and little tenderness.

—Harte, in *Jour. Amer. Med. Asso.*

NORMAL SLEEP, LIKE HYPNOTIC SLEEP, THE RESULT OF THE INHIBITION OF INTELLECTUAL ACTIVITY (Brown-Séquard).—In the researches which I published in 1882 upon inhibition and its rôle in hypnotism I have already shown that hypnotic sleep is an effect of inhibition. Besides, in many publications, but especially in a communication to the Academy of Sciences, I have demonstrated that in epilepsy, and in the organic affections, or traumatic lesions of the encephalus, the loss of temporary consciousness is due to an inhibition of intellectual activity. I wish now to show, in a few words, the reasons which lead me to consider normal sleep as the effect of an inhibitory act.

The theory according to which sleep depends upon a vascular contraction taking place in the central lobes (Durham, Hammond) is absolutely false, as I have shown some time since. In effect I have found that guinea-pigs and rabbits, after the section of the two great sympathetic nerves of the neck, sleep as if the cerebral circulation was in its normal state, that is to say, if it ceased by vascular contraction.

It is the same with dogs and cats, after one has cut away the superior cervical ganglion of one side, and the vago-sympathetic on the other. Whilst one has, by these operations, paralyzed the vessels of the neck, it is evident that sleep, which then occurs in the ordinary way, not only does not depend on a cerebral anemia from vascular contraction, but can even exist despite the opposite state, that is, a hyperemia even notable. It is certain, then, that sleep can exist, whether there is little or much blood in the cervical vessels.

The loss of consciousness during sleep, as in many other circumstances, accidental or pathological, is the effect of an inhibition of the cerebral faculties.

I rely to prove this opinion upon: 1. Direct proofs establishing that the loss of consciousness, in case of a wound of the bulb, and also in other cases, is incontestably due to an inhibitory act. 2. All that is known of the circumstances preceding or accompanying sleep.

I limit myself to saying on this subject that, as in all inhibition, there exists, while sleep is produced and continues, irritations from a distance of the organ where the cessation of activity has place. The proof of the existence of irritations is found in the following particulars:

1. What is called "the need of sleep," consisting of certain sensations, especially a heaviness of the eye.
2. Persistent contraction of the eye.
3. Contraction of the orbicular palpebral muscles.
4. Contraction of the internal and superior recti muscles.
5. Contraction of the blood-vessels of the retina and cerebral lobes.

I add that besides the inhibition of the psychic faculties there is a special inhibition of certain muscles (lavator palpebræ superioris and the muscles of the neck), and perhaps also an inhibition of the heart and the respiration. These different inhibitory phenomena, associated with sleep, show plainly the existence of an irritation of some part, or perhaps at many points, during that periodic state of cessation of intellectual activity.

The production of sleep with man, according to Fleming and Augustus Waller, depending upon a pressure exercised at once upon the carotid, the cervical sympathetic, and the vagus nerve, shows well that sleep can be produced by a peripheral irritation.

As to the ordinary seat of the irritation or irritations which cause sleep, I can say no more than this: (1) It is improbable that this can be in the brain, properly speaking, for, as we know, birds, and especially pigeons, sleep and awake periodically, after the ablation of their brain as well as before; (2) the reflex contractions and paralytic inhibitions which are associated with sleep, if we consider them as due to irritations proceeding from the same point, have their seat much more probably in the excitable parts of the base of the brain rather than in the cerebral lobes.

Before concluding, I will recall that in epilepsy which I produced in guinea-pigs, loss of consciousness, like the convulsions, is easily caused by a peripheric irritation, and that this occurs often in attacks of petitmal in man. I recall, also, that the loss of all cerebral activities could have place, by inhibition, as I have shown, under the influence of irritations even very light, of the base of the encephalon or of the spinal cord, but especially at the point that Flourens has named the vital knot.

It is not doubtful, after all these facts, that irritations of diverse seats exist during sleep, having commenced a little before the moment when slumber supervened. There is then every reason to acknowledge that the principal phenomenon of ordinary sleep, that is to say, the loss of consciousness, is the effect of an inhibitory act.—*Archives de Physiologie.*

PLACENTA PRÆVIA.—At the annual meeting of the North of Ireland Branch of the British Medical Association Dr. Dempsey read the notes of a case of placenta prævia which he had treated successfully by the introduction of a large piece of solid alum up against the os, and maintained in close contact with it by a vaginal tampon. He claimed for it a number of advantages. 1. It produces constriction of the uterine sinuses by hardening and contracting the uterine fibres in the lower segment of the uterus, against the outer surface of which it is in contact. 2. It appears to assist in causing thrombosis of the sinuses. 3. It produces a tenacious mortar-like coagulation of the effused blood, which acts as an additional tampon in the vagina. 4. It does not prevent dilatation; and, 5, from the limited experience of it, it appears to obviate the necessity for the usual operative measures required in placenta prævia until the os is sufficiently dilated to permit of them with safety. In the case in point the patient was a multipara between the seventh and eighth months of pregnancy; active hemorrhage was going on before the introduction of the alum, yet none occurred afterwards, though the placenta was central, and dilatation had proceeded almost to the full extent. The alum had been left in for seventeen hours. Immediately after its removal violent hemorrhage again occurred, but delivery by version was easy of accomplishment without any injury to the maternal structures. Dr. Dempsey also showed a most interesting specimen of placenta prævia where abortion had taken place at the fifth month of gestation, and which had been treated by the same method as the above. The placenta was centrally attached over the os in this case also, and the breech presented; but, owing to the very extensive uterine attachment of the placenta, the fœtus was born enclosed within the placenta. Only a very small portion of the amniotic membrane could be seen on one side of the fœtus like a small window in the placenta. The fundal part of the placenta was the thickest, and the funis was attached to this portion.

—*British Med. Jour.*

Medical News and Miscellany.

FLAT-IRONS are kept hot by electricity.

THE Sanitary Committee of the Board of Health recommended, last week, several unhealthy school-houses to be renovated.

THE famous Bath Springs House in Bristol, Pa., will shortly be torn down. It has been a noted house since its erection, in 1810.

MILTON J. ROSENAU, of Pennsylvania, has been nominated by the President to be Assistant Surgeon in the Marine Hospital Service.

THE use of pepper as a medicine was common in the days of Hippocrates, who applied it moisoned with alcohol to the skin of the patient.

A YOUNG daughter of Dr. Howard Pursell fell from the portico of her home, a distance of fifteen feet, one day last week, and was seriously injured.

DR. H. P. EVES, the State Veterinary Surgeon of Delaware, reports that the disease which has recently caused the death of a large number of cattle in the vicinity of Wilmington, and which was supposed to be Texas fever, was hydrophobia.

THE appointment of Dr. Baxter as Surgeon-General of the Army Medical Corps will be received with pleasure by the entire medical profession.

THE Pennsylvania and Maryland Union Medical Association will hold their tenth annual re-union at York, Pa., on Thursday, August 28, 1890.

DR. O. SAWYER, of Chicago, was shot, and it is feared fatally wounded, last week by J. Barton Sancher during a fight growing out of domestic troubles.

THE Medical College of South Carolina has formed into line and is recommending, and wishes to make obligatory, a three years' graded course to their students.

A SHERIFF seized a Western college for debt some time ago, and an inventory led to the discovery that the assets consisted of a first-class yell.—*Binghamton Leader.*

DR. SAMUEL MERRITT, the wealthiest citizen of Oakland, Cal., died on August 17. It is needless to add that his wealth was not acquired by the practice of medicine.

LAST week the public baths were patronized by 8,234 men, 105 women, 514 girls, and 46,242 boys. This will fairly represent the love of cleanliness in these classes.

FIVE persons have died at Nicolaieff from Asiatic cholera; eleven cases have been reported, and the Porte has decided to quarantine all arrivals from places on the Black Sea.

THIEVES attempted to enter the residence of Dr. L. D. Bauer, at Fifth and Fairmount, on the morning of August 18; but, hearing the doctor's stentorian voice, they left in a hurry.

THE cholera epidemic seems to be diminishing in Valencia and Toledo, but one hundred and seventeen deaths from it occurred one day last week in Mecca, and seventy-nine in Jeddah.

IT is commonly believed that the tendency to suicide, like the tendency to madness, runs in families; but a man may bring this tendency on by an overestimate of his working powers.

DR. G. W. CAMPBELL, of Newport, Pa., has been indorsed for Congress and has also been elected a delegate to the State Convention by the Prohibitionists of Perry County at New Bloomfield.

THE seventh annual report of the State Committee on Lunacy was issued last week. The report is made to the Board of Public Charities of the State, and is for the year ending September 30, 1889.

THE *Lancet*, discussing the Kemmler execution, says: "The operators in the Kemmler case used their mimic lightning with all the clumsiness of mortal inability. They burned the skull and a portion of the back, and exploded the sinuses of the brain. No doubt they were fortunate enough to render the man senseless at the first blow, just as they would have done if they had struck him on the head and back with a red hot hammer; but there was found no mark of the electrical current in or through the viscera of the body. The man was killed by concussion of the brain and explosion within the closed cavity of the skull, just as a man may be killed by apoplexy or sunstroke."

During a thunderstorm in Houghton county, Michigan, a Mrs. Kapper received a pretty strong dose of electric fluid. She had been suffering greatly from inflammatory rheumatism, but since the shock has not felt a single pain.

Dr. Wetherill, of the State Board of Lunacy, is giving earnest attention to the subject of help for the insane in time of panic or fire. At present every cell must be visited and unlocked, while the windows are permanently and strongly barred.

At the Southwestern Dispensary, the following number of cases were treated during the month of July: Medical, 136; surgical, 21; gynæcological, 20; diseases of the nose and throat, 14; diseases of the eye, 91; making a total of 282 cases.

Dr. W. F. Hern, of Carlisle, Pa., found a large amount of arsenic in the stomach of Mrs. Rebecca Gompher of that place, who is said to have been poisoned by her husband. He filed a sealed report of his investigation in the County Commissioner's office.

Now that the Kemmler execution is a thing of the past, it beats all creation how many of the I-told-you-so wiseacres knew beforehand that it would be an awkward and painful affair. The ex post facto prophet is just now on particularly good terms with himself.

In his Address on Surgery, Tait suggested that the medical student should take lessons from the carpenter and the blacksmith upon the way to use the saw, the hammer, etc. Judging by some operating we have heard of, the instruction had been limited to these handicraftsmen.

A Chemical Union, the aim of which is to monopolize the trade in chemicals, has been definitely formed. The union has a capital of $40,000,000, and proposes the production yearly of 150,000 tons of bleaching powder, 180,000 tons of caustic soda, and 300,000 tons of other alkalies.

Nursing Poison Again.—A case is reported in the *Australian Medical Gazette*, of a woman who, on taking a dose of chlorodyne for the relief of pain, soon after suckled her twin babies. The children were found the following morning profoundly narcotized, and died before evening.

A so-called doctor of Galicia, Austria, burned the bones of two Jewish children in the apartments of a person suffering from typhus fever, thus pretending to cure the disease. He succeeded in nearly smothering the patient, but it is not stated whether the patient recovered. The "doctor" was imprisoned.

The first of the Second Series of Health Talks, under the direction of the National Women's Health Association, was given in the lecture-room of St. Paul's Church, on Thursday afternoon of last week, by Dr. Caroline M. Dodson, the subject being "The Care of Infants and Young Children during the Heated Term."

Sister Gertrude, of Kalihi Rec. Station, Oahu, Hawaiian Islands, thinks much of the malignity of leprosy can be arrested by the help of a good physician with a practical knowledge of all the drugs of the pharmacopœia, their action, affinities, etc., and a further knowledge of many cutaneous diseases and efficacious remedies.

Dr. Thomas B. Reed, accompanied by his wife and three daughters, is spending his vacation at Berkeley Springs, West Virginia; the doctor expects to remain at the Springs until September, when he will return to his summer residence at Media, from which he comes to the city each day, to look after the large practice which he enjoys.

Dr. S. Weir Mitchell, of Philadelphia, recently received from a woman patient the singular present of a cord of white-oak wood, chopped down and sawed up by her own hands. He had recommended to her an active outdoor life in the woods for nervous invalidism. She had followed his directions, with results of which the cord of sawed wood was one of the evidences.

Dr. Allan McLane Hamilton, who has studied and written since 1873 on the application of electricity to the human body, has, after many experiments, come to the conclusion that electrical execution is a humbug, and openly avows his belief that carbonic acid gas introduced secretly by concealed pipes into a lethal chamber would furnish the ideal of civilized extermination for murderers.

Six years ago there were scarcely a hundred electric motors in operation in the United States for any purpose; to day there are not less than 15,000 motors in use, applied to not less than two hundred different industries, and an industrial revolution is taking place equaling, if not surpassing, in importance that attending the introduction of the steam engine, and marvelous in the rapidity of its growth.

Homes for Nurses.—It is proposed in London to buy and endow a home of rest for nurses, especially those of the London hospitals, who have little opportunity for change or relaxation, or leisurely convalescence after sickness.

A movement is on foot in Brooklyn, to erect a home and hospital for the trained nurses of that city. It is intended to be self-supporting, as is the nurses' house in Boston, which is under the auspices of the Guild of St. Barnabas, for nurses.

Two more feminine doctors have been received into the Faculty of Medicine in Paris. They are Madame Kouindjy, a young Russian, and Mdlle. Marie Roussell, from Rouen. Both read their theses personally before the Faculty, and were applauded warmly by the masculine doctors, who apparently regarded with no disfavor these fair competitors in the ranks of medicine. The Russian "doctress" introduced into her *thèse* a warm eulogy of France and French learning, which called forth naturally the plaudits of the assembly.

The Rev. John A. Mulcahy, of Waterbury, Conn., who is traveling abroad, in a recent letter home, says of the people of Munich, that "they have a great fear of being buried alive, and for that reason, when a person dies the body is placed in a receiving vault, where it is kept for four days, and, under the method now used, a sponge is placed in one of the dead persons hands, which is connected by a copper wire with a battery and alarm signal; the hand is fastened tightly around the sponge, and at the least sign of returning animation the alarm is sounded, and the sentries, some of whom are always on duty, respond at once. In the last fifty years there have been thirty-four persons resuscitated by means of precautions of this kind."

MADAME CHARLOTTE BOURNONVILLE, of this city, who died recently, was the mother of Dr. A. C. Bournonville, and the widow of Dr. Anthony Bournonville, Past Grand Master of F. and A. M. of the State of Pennsylvania. During the war she was one of the most efficient ladies' aids attached to the Fifth Street United States Army Hospital. After the battle of Gettysburg she went to the field, and aided with supplies the sick and wounded soldiers. She was a native of France, and had resided in Philadelphia the past seventy-five years.

NEW PATENTS:—

PATENTS GRANTED AUGUST 12, 1890

Atomizer	P. J. McElroy	Cambridge, Mass.
Hospital bedstead	F. L. Bryant	Chicago, Ill.
Capsule-dryer	T. C. Merz	Detroit, Mich.
Nitro-cellulose	G. M. Mowbray	North Adams, Mass. (Two patents.)
Spray-diffuser	E. W. Mackenzie-Hughes	Chicago, Ill.
Truss	Brownlow & Warner.	Ogdensburg, N. Y.

TRADE-MARKS ISSUED AUGUST 12, 1890.

Rheumatic liniment (The word "Rheumaticide" in red letters and in a curved line)	Smith & Parr	Washington, D. C.
Remedies for diseases of the throat and lungs (The word "Broncha" in script letters)	T. V. Sords	Cleveland, O.
Oil of lemon (The word "Limoniano")	Dodge & Olcott	New York, N. Y.
Oil of bergamot (The word "Bergamottino")	Dodge & Olcott	New York, N. Y.
Oil of orange (The word "Aranciano")	Dodge & Olcott	New York, N. Y.
Blackberry brandy (A monogram of the registrant's firm "R. Bros" surrounded by a wreath composed of a blackberry vine)	Rheinstrom Bros.	Cincinnati, O.
Remedy for certain named diseases (The words "Bureau of American Remedies")	S. E. Root	Rochester, N. H.

LABELS ISSUED AUGUST 12, 1890.

"Mrs. L. Schmidt & Co's Healing Liniment"	Mrs. L. Schmidt & Co.	New York.
"Almond Nut Salve" and "Almond Nut Cream"	Mary E. Murray	Chicago, Ill.

—Charles J. Gooch, *Patent Attorney.*

WASHINGTON, D. C.

THE State Board of Health of Pennsylvania have issued a series of circulars entitled "Precautions against Consumption," "Precautions against Contagious and Infectious Diseases," "Precautions against Typhoid Fever," "Precautions against Scarlet Fever," and "School Hygiene." These circulars are of a very instructive character, and will be of value both to the physician and the general public. Copies of these papers can be obtained by inclosing a two-cent postage stamp to Dr. Benjamin Lee, Secretary of the Board, Philadelphia.

TO CONTRIBUTORS AND CORRESPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the U. S. Navy for the week ending August 16, 1890.

WALES, P. S., Medical Director. Detached from Medical Examining Board, and to resume present duty at Museum of Hygiene.

AMES, H. E., Passed Assistant-Surgeon. Ordered as member of Medical Examining Board, in addition to present duty.

SAYRE, J. S., Passed Assistant-Surgeon. Detached from Navy Yard, New York, and to the U. S. S. "Ranger."

NORTH, J. H., JR., Assistant-Surgeon. Ordered to the Navy Yard, New York.

BARBER, G. H., Assistant-Surgeon. Detached from the U. S. Receiving-ship "Vermont," and to the "Pensacola."

VON WEDEKIND, L. L., Assistant-Surgeon. Detached from the "Pensacola, and to the "Vermont."

AUZAL, E. W., Passed Assistant-Surgeon. To temporary duty at Naval Academy, to examine candidates.

FITTS, H. B., Passed Assistant-Surgeon. Detached from the U. S. S. "Pinta," proceed home, and wait orders.

STONE, E. P., Passed Assistant-Surgeon. Detached from the U. S. S. "Independence," and to the "Pinta."

WHITFIELD, J. M., Assistant-Surgeon. Detached from the Monitors, and to Naval Hospital, Norfolk.

AYERS, JOSEPH, Surgeon. Ordered to Naval Academy, to examine candidates for admission.

BRIGHT, GEO. A., Surgeon. Ordered to Naval Academy, to examine candidates for admission.

SMITH, GEO. T., Assistant-Surgeon. Detached from Naval Hospital, Norfolk, and to U. S. S. "Independence."

WHITE, S. S., Passed Assistant-Surgeon. Detached from Marine, and to the Naval, Rendezvous, San Francisco, Cal.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service from July 26, 1890, to August 12, 1890.

SAWTELLE, H. W., Surgeon. Granted leave of absence for fifteen days, Aug. 8, 1890.

WHEELER, W. A., Passed Assistant-Surgeon. Granted leave of absence for thirty days, Aug. 5, 1890.

CARMICHAEL, D. A., Passed Assistant-Surgeon. Granted leave of absence for thirty days, Aug. 2, 1890.

PECKHAM, C. T., Passed Assistant-Surgeon. Granted leave of absence for thirty days, July 28, 1890.

AMES, R. P. M., Passed Assistant-Surgeon. Granted leave of absence for fourteen days, Aug. –, 1890. To proceed to Shreveport, La., as inspector, Aug. 5, 1890.

KALLOCH, P. C., Passed Assistant-Surgeon. Granted leave of absence for seven days, July –, 1890.

PERRY, J. C., Assistant-Surgeon. To proceed to Wilmington, N. C., for temporary duty, July 31, 1890.

SMITH, A. C., Assistant-Surgeon. Granted leave of absence for thirty days, Aug. 11, 1890.

YOUNG, G. B., Assistant-Surgeon. Leave of absence extended twenty days, on account of sickness, Aug. 2, 1890. Upon expiration of leave, to proceed to New Orleans, La., for temporary duty, Aug. 8, 1890.

STIMPSON, W. G., Assistant-Surgeon. When relieved at Buffalo, N. Y., to proceed to Norfolk, Va., for temporary duty, Aug. 5, 1890.

PREVENTIVE INOCULATION.[1]

BY FRANK S. BILLINGS.

PREVENTIVE inoculation is an unquestionable possibility in all diseases of a non-recurrent character. Nature has indicated this fact for hundreds of years, but man has scarcely learned to appreciate it. We start upon an already open path. At its very entrance we can see the guide-post "non-recurrent." To pass on to success requires simply honest and heroic workers. The spirit of a common humanity should rule where greed for the almighty dollar now reigns supreme. The nation itself must be educated to an appreciation of what can be done; then success will come. Only heroes can do such work. The present reign of mediocrity and unprincipled selfishness in our laboratories must be crushed. Better anarchy than the existing conditions! Fraud rules in the place of scientific honesty. Salary grabbers occupy places which should be filled by original investigators with the true scientific spirit. No mind but a free one can investigate correctly.

The Difference Between Experimental and Preventive Inoculation.—These two procedures must be most sharply differentiated. While preventive inoculation must necessarily depend upon experimental for its perfection, we have no need to resort to it to demonstrate prophylaxis by this method to be a possible fact. Preventive inoculation does not depend upon experimental for its demonstration as a possibility. Nature has already done that, as mentioned.

The True Value of Experimental Inoculation.—What do we mean by experimental inoculation? Let us thoroughly understand that first.

By experimental inoculation we simply mean the transference of the disease products (or, pure cultivations of the micro-organismal cause of a given disease) from diseased to healthy individuals of the same, or other species of animal life, in order to see what the results may be.

It is an attempt at transference, nothing more.

The success of such an experiment is determined entirely by the nutrition offered, by the animals inoculated, to the germs of the disease inoculated.

The amount of imbecile nonsense which has crept into medical literature upon this subject is almost indescribable. Koch and his school are almost entirely to blame for it. It shows an utter want of true pathological knowledge and philosophical acumen. It is entirely wanting in sequential logic.

It has been assumed that experimental inoculation in small animals must of necessity determine the real nature of the disease of the animal from which they were inoculated. Such a hypothesis is absolutely absurd. It need not necessarily determine anything of the kind.

These writers do not know the logical definition of the word *contagious*. While they frequently write deftly about "faculative" and "obligatory parasites," their language in regard to the results of experimental inoculation shows that they use words without knowing their logical application. They speak of the "contagion of anthrax" (a faculative parasitic disease), and the "contagion of glanders" (an obligatory parasitic disease), in the same breath. Logically speaking, the word "contagious" simply means the coming in contact with an infectious principle, utterly regardless of its origin. It may be a syphilitic person in one case, and a filth hole in the ground in another. Both may be equally "contagious," but the inficiens in each case had a different origin. This, and this alone, must decide the nature of a disease. They must, of necessity, be either ex- or endogenous primarily. Practically, all

[1] Read before the Section for State Medicine at the Annual Meeting of the American Medical Association, Nashville, Tenn., May 22, 1890; and the Chicago Medical Society, June 2, 1890.

physicians and hygienists know what they mean by a "contagious" disease. They mean that a diseased individual must be, or has been, present of a given species of animal life as its primary source of origin. Historically, we know of no other primary genesis for these diseases. We know that no individual can acquire syphilis, or glanders, or scarlet, or mumps, unless an individual having been afflicted with one of these diseases has been in the immediate vicinity. The closeness of the contact necessarily varies in different diseases. Remove such diseased individuals, clean up or destroy their belongings, and the danger of contagion is removed.

Experimental inoculation cannot strengthen the case in the least degree. The endogenous character of such diseases, that they were strictly contagious in the practical sense, was known centuries before a bacterium was ever heard of. Only bacterio-fanatics seem to be ignorant of this fact. Inoculation of small animals cannot strengthen it an iota. To ignorant minds it might weaken the practical every-day evidence. All animals are not equally susceptible to a given inficiens. Even though experimentally inoculable, a given contagious disease often loses its specific, practical characteristic by inoculation in experimental animals of a given species, but different from that in which it naturally occurs. For instance: glanders, transmitted from a diseased horse to rabbits or guinea-pigs, will not extend, of itself, to uninoculated rabbits or guinea-pigs. It is not contagious in these animals.

A recent writer says that the "crucial test" of the contagiousness of tuberculosis was only obtained when the results of inoculation in rabbits and guinea-pigs had become known. Nonsense! The "crucial test" is the result of contact between diseased and healthy individuals of the species in which a disease naturally occurs, or is naturally transmitted to by accident. According to these absurdly illogical observers of pathological phenomena, syphilis should not be contagious because non-transmissable by inoculation to domestic animals. Why any sane person, looking upon himself as an investigator, especially such an one as Koch, should speak of the contagion of anthrax, swine, plague, diphtheritis, or rabbit septicemia, passes one's comprehension. The latter disease has been especially mentioned, because it is not a natural disease in rabbits, simply to demonstrate the utter absurdity of this position.

The word "contagious" does not properly express the practical and hygienic meaning attached to the diseases to which that name has been given. As repeatedly stated, and as must be definitely understood, it simply means contact with an inficiens, and has no absolutely necessary connection with origin. Let us illustrate this with an example: A physician makes an autopsy on two different people on the same day; the one has perished from syphilis, the other from anthrax. In both cases he accidentally cuts a different finger, and in one becomes a chancre, in the other a malignant pustule develops. Such a thing is possible, but not probable. What has taken place?

Accidental inoculation, through contact with two differently-diseased individuals — contagion. The primary origin of these two diseases has been entirely different, however. The syphilis primarily originated from another individual; the anthrax from the ground of some locality. The one is endogenous, the other exogenous. This at once demonstrates the folly of any further use of the word "contagious" in the differential classification of diseases, as it does not express our true meaning.

To sum up, then, we can logically speak of diseases as extra-organismal, or exogenous; intra-organismal, or endogenous, and sporadic—that is, of undemonstrable origin; or, in other words, from the etiological point of view we can logically only classify diseases according to the primary origin of their cause. Or, to speak with Hueppe, as "obligatory parasites," by which he means that such etiological moments are primarily bound on the conditions offered by some form of animal life for their existence and continuous development; or, in other words, such diseases are "endogenous" in origin, to speak with Pettenkofer, or intra-organismal in origin, as I have termed it.

An endogenous disease is one which, so far as we can historically trace its genesis, has found, and still finds, its locus of primary origin for each new outbreak or extension of the disease in a diseased individual of some given species of animal life (and never in any other way), and then passes directly from the diseased individual to another susceptible, healthy one, either by direct contact or cohabitation, or by contact with some effluvia, secretion, or other material which has either come directly from, or been in immediate contact or relation with, such a diseased individual.

Speaking in the old sense, such a disease would be "contagious." Speaking according to the nonsensical usage of the word at present, no one can tell what its true origin might have been.

In contradistinction to obligatory parasitic diseases, Hueppe has given us the term "faculative parasites," by which he means to indicate diseases of parasitic origin, in which the point of primary development of the germs is invariably outside the animal organism; but they have the faculty of living for a time within the organism of certain species of animal life, becoming parasitic or disease-producing for the time, when such animal organisms offer the necessary nutrient conditions to their life. To this class Pettenkofer has given the name "exogenous," while I have termed them "extra-organismal," or diseases which find their primary origin in external or surrounding conditions. Or, in other words:

An exogenous disease is one which invariably finds its locus of primary origin not in, but outside of, an animal organism; that is, in the earth, or in the surroundings of animal life, where its micro-organismal cause develops under certain conditions of climate and soil, which offer the necessary nutrient conditions to the life and continuous development of its germ.

The infected earth or locality bears the same relation to animal life in the origin of exogenous diseases that the infected animal organism does to healthy susceptible animals in endogenous diseases; that is, they each form centers of primary origin regarding specific diseases in their respective class, but with this difference: *the focus of primary generation, or infection, is fixed in exogenous diseases, while it is movable in endogenous.*

The locus infectionis, that is, the point of primary infection or origin, is contagious in either case. In the one, a healthy susceptible individual must come in direct contact—that is, be upon, or in, such an infected locality, or come in contact with material derived directly from such a locality; while in an endogenous disease the same occurrences must take place in reference to some form of animal life. Hence it is to be readily seen that the word "contagious" has no logical use or place in the nosology of diseases, according to the results of modern methods of investigation.

Preventive Inoculation.—Preventive inoculation is an entirely different procedure. It is based upon a natural phenomenon, viz., that a given disease is non-recurrent in character. But more; that this non recurrent condition of the organism is produced equally as well in the mildest attack of a given disease as in cases in which the diseased individual barely escapes with life. Diseases of this non-recurrent character are small-pox, typhus abdominalis (vulgarly called typhoid fever), measles, mumps, scarlet, whooping-cough, chicken pox, yellow fever, and some others in the human family; and in the domestic animals some of the so-called horse distempers, contagious pleuro-pneumonia in cattle; anthrax, swine-plague, rouget in swine; hen cholera, Southern cattle plague, (Texas fever), and black-leg, and probably the corn-fodder disease, and others.

Some authorities assert that Asiatic cholera is also non-recurrent in character, and I am inclined to think that glanders can be made so by the inoculation of farcy in a mild form. There are probably quite a number of these diseases still unknown to us in the poorly-investigated portions of the globe. I am one of those who, at present, does not believe that rabies is a non-recurrent disease, and hence have no faith in inoculation as a preventive. That non-recurrent diseases can be prevented by inoculation was first discovered in small-pox, and then demonstrated by Pasteur to be possible in anthrax, hen cholera, and rouget, and by Arloing and others in black-leg; by Willems in pleuro-pneumonia in cattle; by Freire in yellow fever in Brazil; by the author in swine-plague, and by Dr. Paquin, of Missouri, in Texas fever in this country. With none of these diseases but small-pox can we claim to have arrived at any perfected method; but still, the immense losses incurred, and the practical results which have followed, warrant the continuation of present methods until others are discovered, or these improved upon. The value of their discovery, and the practical demonstration that inoculation will prevent in the diseases enumerated, cannot be overestimated. It shows what can be done, and will be a stimulus to more extended endeavors. It is my firm belief that before the end of the next century every non-recurrent disease at present known to us will have been brought under the control of preventive inoculation, but more especially those of child-life.

Who can place a monetary value upon such results? Is not the mere possibility of such a result promised, as it is directly, to us by the very non-recurring nature of these plagues of our babes, sufficient to warrant the establishment and maintenance of laboratories for such investigations by our National and States Governments? Is it not the duty and mission of a broad and wise statesmanship to meet this great want? Is not a vigorous and healthy condition of our people the very kernel of a prosperous political economy? Then why are we sleeping? Why is the medical profession so dead to its duty? Is it that a prosperous grave-yard makes plump pocket-books? No! no! It is ignorance and thoughtlessness; but, most of all, a lack of the true, humane, and noble spirit which should dignify the medical profession of a country.

A perfected condition of the human race should be the only ideal to be sought after by the medical profession. Exact and scientific government schools can alone produce this desired condition. Speculative institutions, or any such as depend either in part or in toto upon students' fees for support, can never give anything of value to the country. They may turn out a few competent physicians, but never scientifically qualified ones.

With this introduction, let us turn to the consideration of preventive inoculation once more, especially to its introduction in relation to small pox. We have said that inoculation was the transmission of the products, or cause, of disease from a diseased to a healthy individual. In relation to the prevention of small-pox, this procedure is known as *variolation.*

To repeat: variolation was, or is, the transmission of small-pox itself from diseased persons to healthy ones, by the inoculation of the products of disease themselves. This procedure was first practiced by the Chinese and East Indians, a long time before the birth of Christ; but was not inaugurated in Europe until many centuries later. Small pox itself is produced. Why, then, was it resorted to? Any one at all acquainted with epidemiological history of diseases before this century, especially in the fifteenth, sixteenth, seventeenth, and eighteenth centuries, must know what terrible misery and desolation this plague caused. Many districts, and even cities and towns of considerable extent, were almost depopulated by it.

We of to-day can scarcely form any idea of the ravages of small-pox in Europe in the past centuries; but the quotations of a few figures will at once enlighten us; and when they are compared with the same results of to-day, the benefits of vaccination become at once apparent.

Between 1866 and 1869, 140,000 people died of small-pox in the departments of Bombay and Calcutta; and in all India, in 1874–5, the deaths from this cause were estimated at 500,000; and 200,000 in 1875–6. Between the years 1711 and 1740, 65,000 people are reported to have died from small-pox in England. In 1734, two-thirds of the population of Greenland died--7,000. The deaths from this disease equalled the births at Turin, Italy, from 1796 to 1797. In Prague, Germany, the deaths were 6,686 in 1796, and 15,558 in 1799. In Prussia, 1796, 24,646. In the province of Wurtemberg, in 1790–1800, 36,933. France, from 1726 to 1754, 760,000, of which Condamine says[1] that this number of lives could have been largely saved had there been a general recourse to variolation. In Sweden, from 1749 to 1765, 144,194 deaths from small-pox were reported. In London, in sixty-seven years the deaths from this cause were 113,851; and from 1837 to 1840, 36,000.

Why was variolation resorted to? There must have been some one striking phenomenon in the clinical history of the disease which attracted even the general attention of the common people. What was it? It was the fact that the disease, in general, was "non-recurrent" in character. Outbreaks at that period of the world's history occurred almost constantly, though in some years, or at intervals, to a far more murderous degree than at others. This condition of things soon demonstrated to the people that, as a rule, those who had the disease once seldom suffered a second attack. They had abundant opportunities to test this fact. They also discovered a second fact, which was of far greater importance. They noticed that in years when the disease only appeared here and there among the people, and not as a general epidemic, that it was unusually mild in character; and also, that those catching (contagion) the disease from others generally had the small-pox in the same mild manner. In other words, as in other things in nature, they saw that "like (generally) be-

[1] Memoire sur l'inoculation de la petite-veriole, 1854.

gat like," or that a mild, a non-malignant type of small-pox in one individual generally produced the same character in another, if exposed to infection from the first. As has been intimated, the Chinese, and other Asiatic people, observed this valuable fact centuries before it received any recognition in Europe. They were then well acquainted with several facts in the history of small-pox, which were:

1. That when malignant in its first appearance, it would preserve that character among the whole population.
2. That when mild it held the same course.
3. That it was non-recurrent, as a rule.

This last was a tremendous discovery. These so-called barbarians seem to have been practical enough to endeavor to take advantage of these phenomena. Knowing the difference in the results between a malignant and mild outbreak, and that the disease did not generally recur again in the same individual, and that at no time could those that had not been diseased be safe from its ravages, they took advantage of the mild outbreaks and tried to induce the disease, at such times, in every susceptible member of the community.

The first attempts at transference were those most natural to occur to the untutored mind—non diseased persons were obliged (or did it themselves) to wrap the clothing of diseased ones about them, or the scabs were rubbed on the skin, or upon scarified or wounded places. In India, where the history of variolation seems to extend into the misty and indefinite past, it was entirely in the hands of the Brahmin priests, and hence, acquired a very wide extension. They had certain seasons of the year in which they went among the people for this purpose, who were especially prepared for it, by certain known dietetic regulations. The priest then went from hut to hut variolating the people at the door. The point of attack was the outside of the fore or upper arm. The skin was washed thoroughly and then rubbed hard with a dry cloth at the point selected, small incisions being made in it. The virus inoculated with was from the previous year and dried on cotton, which had been saturated from diseased individuals. They never used fresh material. Variolated people were subject to especial hygienic rules for a period of four weeks.

It is said that the danger from this treatment was so small that it was rare that any one died therefrom. It seldom failed to give protection. In Circassia it was resorted to in the early life of the maidens, in order to preserve them from the scars of the natural disease which would render them unsuitable for sale to the lords of the harem.

From Asia, Arabia and Northern Africa, this procedure finally extended to Europe, by the way of Turkey and Greece, but found the most bitter opposition from the physicians of the time, and the clergy, the chief objection raised being that it was trifling with the will of God to take measures to prevent anything which He caused; that small-pox was a punishment of the Lord's for the sins of humanity, and hence justly deserved. (See De Hæn and other writers of the period. Hæser, "History of Medicine." Bohn, "Handbuch de Vaccination," and other works upon small-pox).

Early in the seventeenth century, however, variolation became a "boom" (if I may be allowed a modern expression) in England, which was instigated by a courageous woman, Lady Montague, the wife of the British Ambassador at Constantinople, where she had seen the procedure and learned of its real benefits. On her return to London, in 1717, she had her six-year-old son variolated, and four years later, her only daughter. This venturesome act set all fashionable London in a whirl of excitement, and by order of the king, six persons that had been condemned to die, were pardoned on condition that they would subject themselves to inoculation, and then be exposed to small-pox. This was done, with the most positive and satisfactory results. Soon afterwards, the children of George I were inoculated, and then the treatment became more or less fashionable.

It is only justice to the fair sex to mention that, to a woman also, the Marchioness Buffalini, is due the generalization of variolation in Italy.

Variolation had two historical periods. The one, beginning, as has been shown, in the earliest days of historical record, and extending to the year 1760. This may be called the Crude Empirical period.

The second, which may be called the period of Exact Scientific Observation, began and continued to the demonstration of vaccination by Jenner, May 14, 1796.

If vaccination had its Jenner, so had variolation its Gatti, to whom the world is equally indebted, for it was almost entirely due to the acute observational powers and logical conclusions of this great Italian physician, that variolation itself became an almost safe and equally valuable prophylactic measure to vaccination. Though there seems to have been no historical connection between the work of Gatti and Jenner, still the one did prepare the way for the other, for Gatti demonstrated most conclusively the almost safe prophylactic power of variolation (to the individual inoculated), and hence, his work gave a substantial and practical foundation to vaccination.

Variolation was the first great and successful experiment in the history of pathology, as well as the very foundation of preventive inoculation. It was the first practical demonstration of the fact that non-recurrent diseases could be actually prevented by artificial inoculation; that the art of man could successfully reproduce the work of nature; that, as in nature, a mild attack of non-recurrent disease occurred, so could man, by the transmission of the disease-product, from such a person to a healthy individual, also produce the same mild disease; and, hence, induce in the inoculated individual that same immune condition which nature produced, under similar circumstances.

The name of the real European founder of such a beneficient procedure should not have been allowed to have been so profoundly buried in the archives of medical history. How many American physicians ever heard of the name of Gatti, and yet it should be kept as fresh in memory and crowned as plentifully with laurels of gratitude, as that of the ever immortal Jenner?

Regarding Gatti's relation to variolation, I will take the liberty of quoting directly from Bohn, who says: "No one penetrated more profoundly into the essentials of variolation than Gatti, and no other succeeded as well as he. Gatti is a wonderful phenomenon in the history of medicine in the past century. Nearly every page of his little book on variolation astonishes one by its richness in ideas and its advance over those ruling in medicine at the time. He was a thoroughly unprejudiced and positive observer, sharp and logical in conclusions, with a clever understanding of the nature of pathological experimentation, and knew how to give the correct answer to questions coming before him. One can have but a very superficial idea of variolation in the previous century who has not studied Gatti's work, which is characterized by its clear method, modesty and great humanity."

Gatti's instructions as to the treatment of persons to be inoculated, carry us back to our youthful days, when we had to be prepared for vaccination with cooling salts and other restrictive dietetic measures. He says: "All physicians have said that the persons to be inoculated must be, first, prepared; second, such inoculation-traumata must be made as to allow for a free outflow of the inoculated material; third, as soon as the eruption appears, the patient must be treated with all the care and assistance possible to the physician. On the contrary, I say; patients need no preparation; the physician should never provide for the outflow of the inoculated material by such wounds; and the inoculated person should be left to nature." "To prepare an individual for inoculation is the same as endeavoring to give him a certain predisposition which one considers necessary in order that the inoculated disease shall do him the least possible harm. Is there such a disposition, or can such be produced? We do not know it and hence cannot produce it. Health itself is the best condition, and this alone has one to consider in variolation. An unhealthy person must be first made well before he can be inoculated, but those who are healthy are already prepared for it. Every special preparation on the part of the physician is, however, dangerous. Only those things must be avoided which are liable to interfere with the health. All conceptions as to the preparation of the individual, all endeavors to purify or refresh the blood, or to prevent the inclination of the blood to inflammation, no soul in the world understands, and all endeavors in these directions can only lead to the injury of the individual."

Of inoculation he says: "The material with which we will inoculate must be introduced into the vascular layer of the dermis. The variola virus is so intensive that the most infinitesimal amount is as serviceable as a great mass. It is sufficient, therefore, to simply scratch the epidermis with a needle moistened with the virus, or push it gently for a short distance under the same. This way was first introduced by the inoculators, mostly women, in Greece and Italy, and gave most satisfactory results. Only the physicians have sought to replace this simple and efficacious method by more artificial ones and complicated apparatus."

The barbarism of the physicians of the time cannot be overestimated. Extensive incisions were made in the flesh and the cavity filled with thread saturated in the secretion of diseased persons, or even pieces of their filthy clothing placed therein and held in place by bandages. In other cases, a whole skein of thread would be soaked in such secretions and drawn through the flesh, as a seton. The terrible results and unfortunate complication of such methods can be well appreciated at present, and the value of Gatti to the world better understood now than ever. His motto was, "Inoculate cleanly and delicately, and all after treatment is unnecessary." It is a matter of question if that advice is not as applicable to-day as when he wrote, even with our improved methods of obtaining virus. I have seen physicians vaccinating the poorer class of school children, use the same lancet to scarrify the arm on one after the other, with no attention given to washing the arm, that in many cases were dirty enough. To my mind such a procedure is criminal carelessness, and does much to bring vaccination into evil repute and furnish just and apparently reasonable objections to its opponents. It suffices to say that Gatti's success as a variolator was phenomenal, and that his reputation extended all over Europe. So great did his skill in diagnosis become that he could almost invariably select the correct type of the disease from which to produce the same mild form in the persons inoculated. Very few pustules followed his treatment, and only slight constitutional disturbances in most cases. In fact it is due to Gatti alone that variolation became a reasonably safe procedure between the year 1760 and the introduction of vaccination by Jenner.

Objections to Variolation.—Variolation was not only resorted to as a strictly prophylactic measure, but also that the march of the disease might be hastened, and every one in a community, not previously diseased, might have it at the same time. Variolated persons were, however, as dangerous to healthy ones as those acquiring the disease in the natural manner. They had the small-pox, and hence could be the means of extending it. Therefore, while most extensively practiced, and in many cases made obligatory by law, on the outbreak of small-pox in a locality, still such places were treated as pest-centers, and all communication between them and the surrounding world was shut off until the disease was declared at an end, and the locality cleansed and disinfected, as best they knew how.

The cleverness of these early variolators cannot be overestimated. They insisted that persons to be inoculated be kept by themselves, or from general intercourse with the people for twelve to fourteen days previous to the operation, in order to avoid, as far as possible, the danger of natural infection. They discovered that early childhood was the best time to inoculate, and also that the virus mitigated somewhat in virulence when transmitted from individual to individual. They also paid strict attention to using the clear lymph before the eruption became pustulous, and even collected it in fine glass tubes for conservation. The crusts were also pulverized and so preserved. They found that certain persons were immune towards variolation, about five in one hundred, which, singularly corresponded with the per centage of immunity noticed in natural outbreaks of small-pox. It is easily to be seen that, at the best, variolation was a somewhat dangerous procedure; not only could it extend the disease, but fatality sometimes followed it, per centage being about one to one hundred. Nevertheless, it was a vast advance in prophylaxis, as can readily be seen by comparison with the death rate from the natural disease. Then again, it was found very difficult to exert a proper control over all the inoculated persons, as they were frequently scattered through the community, thus making centers of danger wherever they might be. Notwithstanding all this, there is no doubt but what it proved a great blessing to humanity, and was the means of saving thousands of lives and much misery.

While variolation was forbidden on the Continent of Europe, soon after the discovery of vaccination, it was continued in England until the year 1840, and practiced fully as much as vaccination, when it was also forbidden. It is still practiced, however, among many of the people of Asia and Africa.

Jennerism.—The word "vaccination" is derived from the Latin word "vaccina," of, or from, a cow, and expresses the transference of the disease known as the cow pox, "vaccina," from cows to man. There has been much discussion in the past as to the true nature and origin of cow-pox, without any uniformity of opinion having been arrived at. To my mind it seems as if the observers were almost entirely without ordinary powers of reflection and the ability to draw sequential conclusions. Variola, or small-pox, has been given different names, according to the

species of animals affected, as V. bovina, equina, ovina, and humana. The fact that the inoculation of an animal of a given species, from one of another species, afflicted with the variola common to it, generally protect the first from either natural infection, or the inoculation of the disease common to its species seem never to have been properly appreciated. To my mind it indicates a common origin, and that there is but one variola.

The two malignant forms are those seen in man and sheep, while in cattle and horses the disease has a benign character. Sheep have been protected against variola by vaccination from cattle, and cattle and human beings by ovination from sheep. In fact, ovination of human beings was once looked upon as fully equivalent, in preventive value, to vaccination.

As has been said, these facts of general prophylactic relations between the various variolas, surely indicate but one original form. Whether that point can ever be distinctly decided may be doubtful, but there is no doubt whatever but what we can at once deny all idiopathic attributes to variola in cattle and horses, and emphatically assert that as diseases sui generis they should have no recognition. In fact, in both cattle and horses, variola fails its one essential characteristic. It is not contagious. Transmission by means of the milkers does not constitute contagion!

The transference, inoculation, of either human or ovine variola to cattle through a continued series of these animals, soon mitigates the virulence, so that when again inoculated upon the original species, the contagious factor has been lost. But this is another most valuable pointer in the direction of the original variola. In the days of variolation the most celebrated observers all agreed that the virus of small-pox itself became mitigated on being transferred from man to man through a large number of generations, or individuals. No such phenomenon as this has ever been observed in sheep-pox. It does not lose in virulence in being passed from sheep to sheep. On the contrary, sheep-pox becomes mitigated by transference in all the animals it has been attempted on, man, cattle, rabbits, goats, and horses, but the contrary experiments have never been essayed. Vaccina has never been carried through sheep for a long series of generations, nor has small-pox, nor the eruption in horses. All this demonstrates one fact, that if every other kind of variola loses in virulence, even by transmission in its own species, (using the accepted idea of specific variola) except that of sheep, then the ovine organism provides the most suitable nutrition for the preservation of virulence alone—contagiosity, the human next, while in cattle and equines it is soon lost altogether.

As a matter ot experiment, and great pathological interest, it is important to endeavor to build up vaccina to contagiosity again in sheep, if it can be done. It is singular that observers should have looked upon the bovine and equine complications as idiopathic, when in the former it is limited almost entirely to cows, and in both is not a natural contagious disease, only extending by accidental transmission.

It is a matter of absolute certainty that vaccina either owes its origin to the human or ovine disease, most probably the former; and that it was transmitted to cows in past ages in some way by milkers, who also took care of their friends diseased with small-pox, and then the eruption was transmitted in the same way, by the milkers, from cow to cow in a herd, and in this way the disease acquired a constant degree of mitigation—in fact, absolutely lost its virulence, or contagiousness, but still retained the prophylactic principle. Right here let me make a statement which seems to have escaped notice, or expression, at least, and which is of the utmost importance in the study of preventive inoculation: What does this peculiar deportment of vaccina teach?

The very fact that the virulence, contagiousness, of small-pox having been lost in the change from variola to vaccina, shows us that the germs of non-recurrent diseases have the ability to produce two different chemical materials—one pathogenic, the other pro phylactic, and that tests of virulence have no value or control in the question of prevention.

Later on we will return to this question in detail.

It seems never to have been properly appreciated, that there is not on record one single eruption of variola in cattle or horses of a general or epizootic character. As a herd disease, under natural or free conditions, we have no record of it. This again tends to support the hypothesis that the disease in these two species found and finds its origin in the small-pox of man, rather than in the variola of sheep.

Again, as strong proof as can be brought to bear in favor of both these suppositions, and of vaccination itself, is given by the fact that, with the generalization, or compulsion of vaccination, not only has small-pox been brought under most wonderful control, but cow-pox has been almost entirely lost sight of. While there have been cases of small-pox every now and again, and sometimes quite a number in a locality, no one ever hears of a case of cow-pox, and seldom of anything causing a suspicion of the same.

Bohn says, that while vaccination had its Jenner, it was never fortunate enough to have had its Gatti, as did variolation. When I read that passage I could not but think that the worthy German had spoken in ignorance, and that vaccination had indeed had one to take part in its development; one the equal of the great Italian in every respect; one whom we should all delight to honor and to whom this country owes a monument of gratitude, if humanity does to any man, in its development on American soil. I allude to the late Dr. Henry A. Martin, of Boston, the introducer of animal vaccination into this country, a man with more sterling manhood, a more honest brain, and the most comprehensive scholar it has been my fortune to meet among the physicians of this country. In fact, I will go farther, and say, that from the stand-point of a fearless manhood and a devoted and true physician, Henry A. Martin was the only whole man I have yet met in the American medical profession. He was no trimmer; no politician; in fact, he was without policy, as every man should be where truth is concerned. Most physicians in this country are trimmers. They "trim" their professional sails to suit the theological or political breeze, or social conditions. Men are so scarce! Dr. Martin spent a great deal of money trying to find a genuine case of genuine cow-pox in this country, and during his many years of earnest study found but just one. I visited some cases of eruptions in the teats of cows with him, and have been called to many others since, but in none of them has the trouble had any close resemblance to vaccina.

It is the general opinion that Jenner discovered vaccination, and it is for that that he has been honored and credited. Jenner's discovery was the humanization of vaccina; animal vaccination, true vaccination, is of much later origin, and owes more to Martin for its generalization than to any one else, but it is not the exclusive right of any one man. Jenner's method was to take vaccina from accidentally inoculated human beings, and then to pass it indefinitely from person to person. Probably the very crusts, or scabs, used on us in our youth, were direct derivatives of those first originated by Jenner.

That cows had an eruption on their teats which could be conveyed to human beings, and which did prevent small-pox in such individuals, was known long before Jenner's time, seems to be a matter beyond all question. Even that vaccination itself was practiced in England by one Benjamin Jesty, on his own wife and child, in 1774, twenty-two years before Jenner inoculated, is equally true. That vaccina in some way was transmitted to dairy people, and prevented small-pox, was also known to the common people in Germany and other parts of Europe, but no practical use was made of the knowledge. It remained for Jenner to do this. Jenner supplied the exact and trustworthy foundation to a matter of popular belief among a certain class of people, but of which the majority had no knowledge. Jenner's work was thoroughly original. There is not a particle of evidence going to show that he knew anything about the vaccination of human beings by a few others before he attempted it. Not one of those men gave any exact study to the subject, while it is said that Jenner studied, and observed, and weighed all the facts for thirty years, before he attempted to prove his observations and fortify his conclusions by direct experiment on man. This was done on a boy named Phipps, the 14th of May, 1796. But this boy was not vaccinated from a cow, but from one Sara Nilmes, who had been accidently inoculated from a cow, being a dairy-maid. The boy resisted all attempts to transfer small-pox to him by variolation.

It is doubtful if Jenner ever resorted to vaccina itself, that is, to a diseased cow, for his original material, but invariably took his stock from human beings. This should be called Jennerism, or Jennerization.

The one striking peculiarity of this and vaccination, in contradistinction to variolation, is, that the inoculated individual is not contagious to its own species. This is a very striking example of the true meaning of the word "contagion," which, as has been discussed elsewhere, seems to be entirely beyond the comprehension of the medical profession and investigators, with but very few exceptions.

Sycophantic worshippers of Robert Koch, and even the Master himself, are respectfully referred to this example, and asked to ponder a moment that they may learn that contagion and inoculability have no necessary relation, that contagion really means, that the point or locus of the primary origin of the inficiens is a diseased individual.

As has been stated, the very strongest examples of the value of vaccination are not only the very few outbreaks of small-pox which now occur, but also the almost total disappearance of cow-pox among the cattle of those people where any exact control of the question can be looked for. Statistics, as to the value of inoculation, can have but little additional importance, still, a few are appended.

TABLE SHOWING THE EFFECTS OF VACCINATION.[1]

Period of observation. Before vac'inat'on	Period of observation. After vac'inat'on	Place of observation.	Average annual death-rate from variola to the million population. Before vaccination.	Average annual death-rate from variola to the million population. After vaccination.

The Utility of Vaccination.—"The deaths from small-pox in Germany, where there is compulsory vaccination, during the years 1887–1888, were 1.8 and 0.8 per million, respectively; while in Austria, where compulsion does not exist, the deaths were 583.7 and 540.4."—*Medical Record*, April 12, 1890.

Vaccination can be very properly termed the use of a natural method of inoculation, even though the virus is now kept up by the artificial transmission of vaccina from calf to calf. It is not the discovery of man. So far as reliable information is at hand, there is no record of the discovery and actual demonstration of the true germ of variola, though the "culture of an artificial vaccine virus, by a Russian physician, which is as effective as the genuine" vaccina, was reported in the issue of January 18, of the *Journal of the American Medical Association*. This assertion must be taken *cum grano salis*, as no mention of such a discovery seems to have been made in any of the special journals of bacteriological research. So far as my memory serves me, nothing but cocci have thus far been discovered in the eruptions of variola or vaccina. I think, when discovered, that the germ of variola will be found to be a very delicate anaërobic bacillus, and spore-bearing at that. Otherwise we cannot account for the long time which clothing, or other material, polluted by small-pox patients, retains its virulence. No non-spore-bearing organism that we now know of retains its virulence for such a length of time under such adverse nutritive conditions. I am also of the opinion that most of the endogenous germs will be found to be anaërobic.

A Few Words as to the Objections to Vaccination.—The opponents of vaccination base their opposition upon the dangers of the transmission of other diseases with which the individual may be afflicted at the time, and from whence the virus has been derived. These objections are more applicable to the transmissions from human beings to human beings than in regard to the use of true vaccina directly. To my mind, however, they will scarcely hold water when we come to consider them critically. Take, for instance, syphilis. If, as is the case, it is at present impossible to positively isolate the germ of that disease, or even to perform auto-inoculation save from a positive syphilitic lesion; if we cannot in any way discover that germ at present—how can it be possible to transmit syphilis from an arm or locus in which there is no syphilitic lesion? It seems to me almost impossible. The same is true of tuberculosis.

[1] Hirsch, Handbuch der Geographischen Pathologie.

The unpleasant complications following vaccination, when scabs were used, or from person to person directly, were due more to some organism which had gained access to the scab from outside, or to the carelessness of the inoculator regarding the cleanliness of his instrument, than to anything else.

The criminally careless manner in which vaccination is done even to day by too many inoculators, has already been noticed, and is absolutely unpardonable in these days of exact antisepsis and in general scrupulously clean surgery. In such a simple matter as this apparently is, many physicians appear to neglect precautions they deem absolutely necessary in their operations. And yet we even now frequently see erysipelatous or purulent complications follow. If the virus is properly collected, these things should never occur.

More precautions than are now used should be taken in the collection of the virus from calves. Why should all the points and instruments used not be completely sterilized? That they are not, goes beyond question.

The generally favorable results following the use of vaccine points by ordinarily careful physicians shows that the danger of unpleasant complications has been altogether overestimated and magnified by those opposing this valuable prophylaxis. Still, as such does exist, it seems as if some control over these matters should be exercised by law.

The danger of using diseased heifers, especially tuberculotic, need not exist, as I know from a long personal acquaintance with the senior and junior Dr. Martin, where every care is used in collecting the stock. The heifers should be collected some time in advance, and their temperature taken twice a day, and a general observation of their condition practiced. Any animal showing the least departure from normality in any direction, should be peremptorily rejected.

We will now for a moment give our attention to

Pasteurism.—The world owes an unpayable debt to Louis Pasteur, for to him is due, more than to any one else, the reopening of the field of experimental preventive inoculation, and in directions never before thought possible of offering any practical advantages. But even he has not touched upon the most important work, which is the prevention of the non-recurrent diseases of child-life, most especially scarlet fever, which is to-day the greatest scourge that threatens humanity in civilized countries. Pasteur is an explorer in an almost unknown sea of investigation. The "gates" are still but "ajar." They are not yet open. Many others are trying to enter. Some few can glance over the threshold, but the haven of success is yet a long way off.

While I do not accept the results of Pasteur's antirabies inoculation, I most cheerfully credit him with his earnest endeavors and the instructive value of his success in anthrax, hen-cholera and rouget in the hog. It may be well for me to state why I do not believe in Pasteur's method of preventing rabies.

1. There is not a particle of evidence to be found in the long historical record of this disease that it is non-recurrent in character. Not a single case of natural recovery in man or beast has ever been reported where the history of its origin was undoubted and the phenomena presented unquestionable. Hence, we have no natural foundation to warrant the hypothetical possibility of preventive inoculation.

2. Pasteur's statistics are not honest. Not one of those Newark children was ever bitten by a mad dog. Two were left at home, and nine or ten dogs known to have been bitten by the suspected dog were kept confined over three months. Nothing ever happened to them. While the dog was "mad" enough, it was not "rabid." It did not seek to bite any one or thing, but did bite those in its way while running. It was a case of simple frenzy from an unknown cause. Dogs are often attacked thus, without rabies having anything to do with it. Pasteur still keeps those children in his statistics, though he has been fully informed as to the true nature of the case.

3. Pasteurism in connection with rabies has become a regular mania in certain parts of Europe, especially France, and rabies or hydrophobia bears a direct relation thereto. This is easily to be seen by glancing at the statistics of rabies in Prussia, for a series of years; viz. :—

1876–7, 0; 1877–8, 6; 1878–9, 2; 1879–80, 8; 1880–1, 10; 1881–2, 6; 1882–3, 4; 1883–4, 1; 1884–5, 0; 1885–6, 2; 1886–7, 1.

All suspected or rabid dogs in Berlin are brought to the Veterinary School. This includes every dog complained of as having bitten a human being. Of this number rabies has actually resulted:

1878–9, in 5; 1879–80, 1; 1880–1, 11; 1881–2, 3; 1882–3, 1; and none since then up to June 23, 1889, when I received my report. In the whole German Empire there were but five cases of hydrophobia reported in man, in 1886; and but four in 1887.

From 1886 to 1888, there were forty cases of hydrophobia reported in Prussia; and in 1886 and '87, only nine in all in Germany.

Now let us look at the statistics given in Pasteur's Annals.

No. persons treated.	Rabies said to have been demonstrated surely.	Diagnosed by veterinarians.	Suspected.	Total.
Dec., 1888.	45	77	20	142
Jan., 1889.	32	88	22	142
Feb., "	52	90	18	160
March, "	42	95	32	169
April, "	30	122	29	181
May, "	28	149	36	213
June, "	24	115	30	169
July, "	19	111	38	173
Aug., "	15	97	33	145
Sept., "	15	80	16	111
Oct., "	19	88	16	123
Nov., "	20	99	16	135
	341	1211	307	1853

The majority of these cases came from France and the French possessions in Algeria. Does any sane person think that there is this vast difference in the prevalence of rabies in human beings between France and Germany? If so, I am not one of them. If so, no more striking example of the inefficiency of the French Government in comparison to that of Germany in its veterinary police service and guardianship of the public health, can be found.

For three years in Nebraska I vainly tried to obtain possession of an actually rabid dog, and while a vast number of dogs were reported to have been bitten by such, not one would go rabid for me after it had been so bitten. I do not deny the disease. I simply deny its prevalence to any such degree as Pasteur's statistics seem to show. I simply do not believe them.

To show how unreflectingly even educated writers will quote such statistics, the following is taken from the TIMES AND REGISTER, of Philadelphia, April 12, 1889: "Pasteurism in Cuba.—At the Bacteriological Laboratory, in Cuba, three hundred and six persons have been treated by the 'double intensive' plan. Of these, only two died, after going through the full course; a mortality of 1.63 per cent. All

these cases were bitten by dogs proved experimentally and clinically to be rabid, *or at any rate* 'suspect.' That the operations were conducted with due conservatism is indicated by the fact that only three hundred and six were inoculated out of seven hundred applicants. The opposition to Pasteur, if it still exists, has dwindled down to an infinitesimal point."

Even in these cases, not one case was known beyond question to have been bitten by an actually rabid dog, for it is admitted that "at any rate, they were 'suspects'" only. And yet the editor says: "The opposition to Pasteur, if it still exists, has dwindled down to an infinitesimal point." "Three hundred and six" persons, scared half to death on suspicion! They were "suspects" only. We can "suspect" most anything to result from treatment based on such a "suspect" foundation. The foundation of "Pasteur's Institutes" should be treated in a most "suspect" manner. They should be treated as institutions of the utmost danger to the public. Hydrophobia, or Pasteurmania, flourishes in direct proportion to their establishment.

Since my return to this country, from that sensational visit to Pasteur with the Newark boys, a very large number of such "suspects" have come to me, or have been brought to me by physicians, to obtain my opinion as to the desirability of "going to see Pasteur." Fifty-two persons is the number I have on record, but there were a few more, notably three, since I have been in Chicago.

"Mad dogs" were very "suspect," according to the story, in each case. I talked to them calmly, ridiculed their fears, and they all left me apparently comforted. Not one went to Pasteur, and I think it can be safely asserted that no hydrophobia resulted, or I should have heard of it and the papers would have been full of it long ere this. There is a vast difference between a "mad dog" and a genuine "rabid" one. The former are frequent enough, the latter are as scarce as honest original investigators in the United States.

There is still another very strong argument against Pasteur's anti-rabidism. The germ of rabies has not been discovered. This fact in itself is not very strong negatively; but when we take into consideration that rabies is a strictly wound infectious disease in optima forma; or, perhaps better, toxic rather than septic; that, as in tetanus and many forms of surgical toxæmia, the toxic producers remain at the locus traumatica, and that the poisoning of the organism takes place from there, and goes on for some time, and that constantly during that period until a certain cumulation of such material in the nervous centers has taken place—it seems to me that the Pasteur-method is self-evidently absurd. The toxic rabies' element must be in solution (the nervous tissues being only saturated with it); and hence, though very abundant perhaps, still, not in such an excessively concentrated amount, in the small piece of cord used that it can produce the effect claimed. There is altogether too much dilution. If correct in the hypothesis that the toxic producer remains local, there can be no increase in the amount of poison introduced, save as made each day. The fact that the germ remains local indicates that in the trauma is the place to look for it, as in tetanus.

Again, where can I find record of one of Pasteur's artificially rabid dogs ever having conveyed the disease to healthy ones, as is the case in the actual disease, by biting?

These objections may seem too very finely drawn to enthusiastic worshippers of Pasteur, but it may yet be found that they have more foundation than appears on their face.

These objections to Pasteur on one point do not detract, however, from the importance of his work to the world in others, in the least. What may one really call Pasteurism? The answer to this question brings us at once to the consideration of

Artificial Preventive Inoculation, which I will discuss entirely from my own point of view, and base my remarks almost wholly upon my own work and its results. Pasteurism differs as much from Jennerism as does artificial preventive inoculation from vaccination, as practiced at present. Jennerism and vaccination consist in the inoculation of the cause of the disease to be prevented thereby, bound upon or mixed up with the products of the disease; that is, as they are found in its specific lesion at a certain period of its development.

Pasteurism, or artificial preventive inoculation, or even inoculation in the most exact sense of modern experimental etiology, is quite another thing. Instead of introducing the cause mixed up with any products of disease, we isolate it therefrom, cultivate it, and, by one of several methods found suitable, so mitigate the virulent activity of the cause, that we can inoculate without serious danger to the individual thus treated.

It has become a generally accepted fact that all infectious diseases are due to a specific cause, which belongs to some specific species of microscopic vegetable life. The scientific class to which these objects belong is the fungi, their special name being bacteria, or, in common parlance, germs. It is not necessary to go into any description of the various varieties of these germs in an article of this kind; still, it is necessary that we know a little something of the manner of action of that class in which we are momentarily especially interested.

The diseases of animals in which Pasteur has been, beyond question, successful in preventing natural infection by his method of inoculation, the names of which have already been given, and to which may be added swine plague, the yellow fever, and Texas fever in cattle, as well as typhoid fever, are all what are known as forms of septicæmia, or blood poison; the specific poison in each case being the direct result of certain unknown physiologic action on the part of the specific germ, which causes each of these diseases. All these diseases have also another attribute in common, viz.: they are extra-organismal in origin; that is, the place of primary development of the specific germ which causes each of these diseases is outside the animal organism, or in the earth or earthy material.

Though he has never to my knowledge stated it, still I think Pasteur should be credited with recognizing the fact that cow-pox was but mitigated smallpox, rendered, as has been said, non-malignant in character by successive generations of transmission from cow to cow in an accidental and unintentional manner. Pasteur endeavors to do this same thing intelligently. He but repeated the lesson thus learned in his first attempts at mitigating the action of the germs of anthrax, hen-cholera, and rouget by experimental inoculation in various species of animals, and he found that while in some species a given germ acquired even more virulence than it possessed when taken from an animal in which it had caused the natural disease, and kept on increasing in virulence for a time as he passed it from animal to animal of a certain species, still, on the other hand, the same procedure in another species of animal, carried on

through a long series, not only caused the germ to lose in virulence, but after a time they acquired a certain standard of mildness, and could be safely used for inoculation.

This was imitating the results in small-pox. Pasteur went further! Such a method as the above is open to the very serious objection that, not only is an almost unlimited number of experimental animals necessary, but the expense would finally be such as to decidedly interfere with any practical benefits resulting. This led Pasteur and others to seek similar results in entirely different directions. They experimented in many ways, but the continued exposure of artificial culture of given germs to a certain degree of temperature, or their development in from two to two and one-half pressures of oxygen for a certain time, have given the best and most trustworthy results. A most singular fact came from these experiments, which was that when once a certain desired degree of mitigated virulence had been obtained by either of these methods, that cultivation of the same germs could then be carried on in the ordinary room temperature for an indefinite period, each succeeding generation retaining the same degree of mitigated virulence as the previous one and the mother culture. The result has shown that a preventive virus against anthrax, rouget, and hen cholera has been successfully made by these investigators, by one or the other of methods mentioned.

For a very valuable account of Chauveau's experiments in mitigating the virulence of bacillus anthracis in this way, see TIMES AND REGISTER, Philadelphia, April, 1890.

Based largely upon the teachings and work of Pasteur nearly all investigators in this important field of research have been of the idea, and generally are at present, that a preventive virus can be obtained by the simple mitigation of the virulence of a germ of a naturally non-recurrent disease by artificial cultivation under certain conditions of heat, or oxygen pressure, or some other method, so that the introduction of such a culture in a given amount, produces simply a mild and non-fatal form of disease.

The practical results of inoculation, or vaccination, seem to confirm this idea. For myself, I was also of the same opinion, until it was completely shattered by most extensive experiences, and apparently positive experimental results.

It is but justice to myself to inform my colleagues, both investigators and physicians, that this business of "preventive inoculation" in swine-plague is not of my own choosing; that I am bitterly opposed to it; that I feel it is disgraceful in one being, or making any pretensions of being, a scientific investigator; that I think and know that all and every result of original research should be the property of the people; and I can truly say that, had I not the remote hope that the rewards of this distasteful business may be such as to enable me to build, equip, and plentifully endow a laboratory and hospitals for the investigation of the non-recurring diseases of child life, where the poorest genius can have free opportunity to study and be educated, or pursue original investigations, that I would have nothing to do with it. I would not continue it for a moment, to enjoy even a handsome business income, but I hope the end desired may be attained, and that the medical profession will eventually justify the unprofessional means on account of the worth of the object attempted.

Self respect forced me to resign my position as investigator in Nebraska, on account of three years of uninterrupted intrigue, and unlimited abuse and opposition excited against me by the Agricultural Department at Washington. No other course was open to me.

This inoculation against swine-plague is a matter of more importance to the advancement of original research in this country than at first may appear to the casual observer. I can safely assert that so much success has been attained, that it can no longer be open to a single doubt. Its actual practical value can only be estimated by large and extensive experiences continued for several years. Its present value and interest is, however, mainly scientific.

Having sufficiently demonstrated that inoculation will prevent swine-plague, as Pasteur's work has been the initiative incentive to all investigations in this direction, so should this result have the same value in this country, and be a stimulus to the most energetic and exact endeavors to develop protective inoculation against other non-recurrent diseases in our live stock, but even more particularly those of our own species. If my work only succeeds in putting this stimulus in such activity that work will be inaugurated and earnestly continued, and lead to the establishment of National and State laboratories, all that I have labored for will be attained, and my life be pronounced a success. My interest is far more in inspiring and inaugurating true original research in this country, than in my personal success as an investigator. If the last can only lead to the first then I am satisfied.

In this paper I unfortunately can only place before the world my failures, as in justice to my financial supporter I cannot publish the methods by which I have obtained success, much as it is my desire to, but something valuable can, I hope, be learned from my failures.

As has been said, I began the search for preventive inoculation in swine-plague on the principle of mitigation of virulence, so as to obtain a virus that would not seriously disturb the hogs, and yet render them immune from disease.

At this time and place I will simply reassert that this has been done, and in so many places and in so many hundreds of animals, that the fact is beyond the possibility of doubt.

From this non-virulent point of view the first desideratum is to obtain a virus, or culture, of a constant degree of mild virulence. As inferred above, various methods have been empirically discovered. Pasteur, as has been seen, used certain forms of animal life at first, carrying the virus from one to another of a given species in which it slowly lost in virulence until it acquired a desired benignity. He also found that an augmentation of virulence, until it acquired an equal constance in malignity, could be produced in some other species of animals. This was too expensive a method to be practiced. He then found that the exposure of the cultures to a certain degree of heat for a certain time would also produce the desired mitigation. Others have proven these observations to be trustworthy. Chauveau works by the oxygen pressure method, and has obtained the same result. We need not discuss others.

The great fact is that once the desired degree of mitigation has been obtained in any virus, that the virus thus obtained can be then cultivated in ordinary media (fluid) outside of those conditions, and that the virus thus obtained will retain this constant degree of mitigated virulence for a long time. If a spore-bearing germ, this condition may be retained almost indefinitely, but in non-spore-bearing organisms it is not so reliably constant. The first thing, then,

was to obtain a constancy of virulence in the desired direction.

I have never thought that either of the above methods was strictly scientific. They are too artificial; hence, as far as swine-plague is concerned, I have endeavored to produce the same result by a more natural procedure. That is, by chemical nutrition, for this virulence is entirely a physiological-chemical result, and absolutely dependent upon the nutritive qualities of the media in which germs develop. It has been said that, once a desired degree of mitigation was arrived at, it could be retained in artificial cultures for an indefinite period.

With regard to the swine-plague germ, other investigators have not only declared this to be impossible, but also unnecessary. I shall show that it can be successfully done, but cannot, unfortunately, tell how, for reasons previously given. I think I shall also be able to show that, in a certain sense, no great result has been obtained when we have done it.

Attention has been called to the fact that others could not obtain this constancy in mitigated virulence, and, furthermore, that it was unnecessary in swine-plague.

In a paper on "Hog-Cholera," which is the disease I call "Swine-Plague," one of these diletants says: "I shall not go into the details of preventive measures in this paper. * * * What you are doubtless interested in, is the new points which may have been brought out by our investigations. The most interesting of these is our attempt to confer immunity by inoculation. We soon found that there was no indication for attenuating the virus for this purpose, because the strongest virus might be introduced hypodermically, with impunity, in considerable doses. Now, as the stronger a virus is, the higher the degree of immunity it produces, you can see that there is every reason for using fresh unattenuated cultures. We made many experiments, and found that hogs might safely be inoculated with one-quarter to one-half a ccm. for the first dose, and that the second dose might be safely increased to two to three ccms., showing that some degree of immunity had been gained. Those twice inoculated, however, were still unable to stand exposure in an infected pen, and could not be fed the virus without fatal results."—*Journal of Comparative Medicine.* Philadelphia, Pa., April, 1888, Vol. IX, p. 149.

Let us consider these statements a little. First, not only their general tenor, but that of all the subsequent publications of the same author, show, according to him, that swine-plague cannot be prevented by inoculation. It is interesting to read, in this connection, what the same authority said in 1883, five years previous to the above, when, as can be shown, he had no idea what the germ of swine-plague was; but, supporting himself on the authority of Pasteur, he asserted a micro-coccus to be that cause. Swine-plague was not discovered in France until 1887.

He said: "Our investigations have shown that the plague is a non recurrent fever, and that the germs might be cultivated; they have even proved that these germs may be made to lose their virulent qualities and produce a mild infection. Surely we have here sufficient evidence to show that a reliable vaccine might be easily prepared if we carried our investigation but a little way farther.

"Mr. Pasteur has recently confirmed (?) our American investigations in a very complete manner. He shows that the disease is produced by a micro coccus; that it is non-recurrent; that the virus may be attenuated, and protected from subsequent attacks, and he promises a vaccine by spring."—Report Department of Agriculture. 1883, page 57.

That the above was made out of whole cloth is shown by the following:

First. A micro-coccus is not the cause of swine-plague.

Second. The government knew of only one swine-plague until 1886, and a coccus is not the cause of either hog-cholera, or the nondescript disease it now calls swine-plague.

Third. Pasteur studied "rouget," and not swine-plague.

Fourth. A bacillus has been proven to be the cause of "rouget," and not a micro-coccus.

Fifth. Pasteur's virus against rouget does prevent.

Sixth. If in 1883, this person said: "Surely we had sufficient evidence to show that a reliable virus might be easily prepared," what has become of that evidence since then? It is singular that my success in preventive inoculation should dispel it as easily as the morning sun does the fog of the prairie.

As to preventive inoculation in swine-plague I will quote the following only from my address before the Live-Stock Breeders' Association, of Nebraska, February last:

"My only sin has been that I forestalled the ambition of the government, which being one 'for the people,' we might suppose would be an act to receive kind endorsement rather than the most bitter and fanatical opposition.

"Even that 'Board of Inquiry' admitted that inoculated hogs stood the tests they were exposed to better than hogs which had recovered from a natural outbreak.

"Professor Burrill, in a moment of unprejudiced honesty, wrote me that 'none stood the tests so well as the Nebraska hogs.'

"With these facts publicly announced to those most and directly interested, a political neophyte, in a recent publication, claims that he has a letter from the president of that 'Board of Inquiry,' Dr. Shakespeare, in which the latter says that the Nebraska hogs were equally sick, when put in a diseased herd, with a lot of healthy ones also put in the same herd. Then why did not Dr. Shakespeare tell the farmers that in the published report?

"Was it not the sacred duty which he owed to science and to every hog raiser in this country?

"On the contrary, that part of the report to which he had his name attached says, without any reservation whatever, that the Nebraska hogs stood the tests better than those naturally recovered.

"What more then, can you ask?

"Does not that assertion of Dr. Shakespeare's, indorsed by Prof. Burrill's signature, and by his later letter, not only emphasize and confirm the reiterated statement of the government, that the disease is 'non-recurrent?'

"If the inoculated hogs stood the tests better than recovered hogs from a naturally 'non-recurrence' disease, then art beats nature, and inoculation has proven to be a reliable fact, one established beyond question, no matter if an occasional failure does occur, as it has in my practice since I left you, and since I have had to entrust the business to other hands, and, from the very opposition of the government, resort to an undue precaution, which, had I remained here, would never have been necessary."

To the above I add one testimonial from a practical farmer, contributed to the *Breeder's Gazette*, of April 2, 1890:

"Mr. R. C. Fulton, Taylorville, Ill., writes: 'The reports in your issue of March 19, by C. A. Cantine, A. R. Hubbard, Marion Ryman, on inoculation, remind me that it is surely due Dr. F. S. Billings, also the farming world, that I should make report of my experience with two inoculated boars sent me for the purpose of proving, so far as possible, that inoculation is a preventive. The pair of hogs were received about February 8, and at once placed in the lot of about one acre, adjoining which were breeding pens for six sows. In the lot and pens named I had lost forty head of hogs, and yet had a few left when the boars were placed in pens. These hogs have continuously bedded on the same litter, and in the same pen where eight had laid while sick and dying. I have them fed on ear corn only, and that was strewn on the excrement and cleanings from other infected pens, and for drink they have had slough water, which catches the waste of barn, lot and pens above named. This I consider a crucial test, and I felt nothing short of that would satisfy even my unprejudiced mind as to the prevention of swine-plague by inoculation. Many of my neighbors have looked on incredulously, and I was even laughed at by my more verdant ones; but the laugh ceased; incredulity has vanished, and all admit that something prevented, and what else but inoculation? For my herds have been reduced or swept away before. In conclusion, the hogs named are doing fine on the same ground where forty died.'"

Scientifically speaking, this is sufficient evidence to prove the fact.

Now, as to that irresponsible statement that "we soon found that there was no indication for attenuating the virus, because the strongest virus might be induced with impunity in considerable doses."

Whether one ccm. is to be looked upon as a "considerable dose" or not I will not attempt to decide, but that I can select an outbreak of swine-plague from which that dose, in the first generation of cultivation, will produce fatal effects, as well as that inoculation will prevent, is shown by the following:

In December, 1888, I desired to test a number of inoculated hogs for a special purpose. At the State Penitentiary there raged one of the most malignant outbreaks on record. By malignant I mean acutely fatal, not prolonged, and still fatal in its course. From one of these hogs I obtained a culture and inoculated, in the flank, seventeen healthy uninoculated hogs, and twenty inoculated ones, with one ccm. of the first culture, Fifteen of the uninoculated pigs died, and all were sick. The others were not affected at all. Cultures from the original penitentiary hog, and from several of those which died, with full autopsy notes, were sent to Professor Welch, of Johns Hopkins.

This, then, shows that "considerable doses" of the strongest virus cannot be used with impunity, and also that immunity can be produced by mitigated cultures, as none of the inoculated hogs were made seriously ill during their treatment.

The germ of swine-plague varies very much in acuteness of virulence, as every one knows, and this is shown in nearly every outbreak one studies. Rabbits have been considered to be suitable animals to control this point, of which one observer says: "Rabbits die from hog-cholera inoculations in six to nine days."—*Journal Com. Med.*, e. c., p. 133. On this point Welch says: "The duration of life after inoculation of rabbits is usually from five to fourteen days, and it may be even longer."—*Journal Com. Med.*, Vol. I, 1890, p. 52. "Rabbits when inoculated die usually in six to eight days."—*Bulletin, Johns Hopkins University*, December, 1889.

In an attack upon preventive inoculation, made by a tool of the government before the Kansas Board of Agriculture, we find the following interesting passages:

1. "Prevention by inoculation depends upon the well-known principle that one attack of a contagious disease generally protects the individual from the subsequent attacks of that contagion. All individuals, however, are not protected in this way from any disease, and in many cases the protection only lasts for a short period."

Comment is unnecessary.

2. "The dose is not the only factor which must be considered when inoculating. The strength of the virus varies in different outbreaks of the disease so much that the dose, which would be perfectly harmless in one case, would be as certainly fatal in another. As there is no reliable test of the strength of virus, but experiments upon hogs, and as the strength varies during artificial cultivation, you will see that it is next to impossible to accurately know the strength of the virus he (Billings) is using."

3. "Inoculation in practice consists in injecting under the skin as much of the strong virus of hog-cholera as can be safely given without producing a fatal type of disease. It must be remembered that inoculation is very different from vaccination. The virus used in inoculation is the same as is found in hogs dying of the plague, while in vaccination a virus is used so weakened that it cannot cause a fatal disease. No method of vaccination has yet been introduced for hog cholera. It is inoculation that is being advertised as a preventive for hog-cholera, and it is a question of the size of the dose whether the disturbance produced in the hog's body is mild or fatal in character."

From all that has been quoted from these authorities it is evident that they have no idea of a constancy of virulence in the swine-plague bacilli, or that such can be obtained.

It has already been stated that in Pasteur's and other methods of mitigation, when a certain desired degree of mitigated virulence had been once obtained, cultures of the same degree could be then carried on for an indefinite period.

This led me to the study of the following questions:

1. Is there a mitigated or non-fatal degree of virulence to be found in natural outbreaks? or, in other words, can a vaccine virus be at once obtained from a natural outbreak? This I proved to be an unquestionable fact, easy of demonstration at any time, though it took much study and very close observation of the relation of certain pathological lesions to the desired degree of virulence to obtain the knowledge, and some experimentation to prove it.

2. Can this or any natural degree of virulence be retained indefinitely by any method of artificial cultivation by nutritive measures alone?

3. Can this micro-organism be fed up and down in virulence by changes in nutrition alone?

4. Can a direct proportional relation be established between a certain dose of virus of known virulence in small animals and a safe or preventive dose of the same virus in hogs?

The three last questions have all been solved in a most exact and satisfactory manner.

It is possible for me to almost invariably select an outbreak of swine-plague from which a given dose of the first cultivation will kill a rabbit on subcutane-

ous inoculation in approximately four days, and, by a very slight variation in nutrition, to bring and retain such a virus to this point of virulence in a very few generations.

In order to demonstrate this point, I will give the result with several viruses:

From the first generation of this virus No. 5, seven healthy hogs received one cubic centimeter in the inside of the thigh subcutaneously; two of these died, which were closely confined, within ten days; the others were at first loosely confined, and showed no ill effects; but after the fifteenth day they were changed to the closest confinement possible, and all died between the thirtieth and thirty-fifth days; while five others, which were given plenty of room to roam about, and which received the same dose, all lived. This experiment was made to demonstrate, if possible, a certain well known fact of practical experience.

It has always been told me that if such hogs were shipped, that the death-rate would be checked, or even stopped, while on the cars; and it has also become more or less current among farmers that to put sick hogs on a wagon and rattle them over frozen and rough ground was a good thing to do. In some few cases evil results have followed inoculation. Some few hogs have either died after a prolonged illness or become somewhat stunted; while others, inoculated with the same dose of the same virus, have shown no ill effect. It therefore becomes an interesting question to discover why this should occur in one case, and not in a great many others.

After very careful inquiry it was discovered that, where ill effects followed inoculation, the animals were kept very closely confined, and had not room enough to move around, and that this was the cause; or, in other words, insufficient movement to stimulate the circulation. A very striking example of this occurred in two bunches of hogs inoculated at the same time for a gentleman who is a personal friend and a great advocate of inoculation. At his house were twenty-five hogs in a small pen, while in a field, running with his cattle, were about one hundred and twenty-five others. Those in the small pen had a prolonged and very severe attack of swine-plague in consequence of the inoculation, though none died; while the one hundred and twenty-five in the field showed no ill effects whatever.

Exactly the same thing occurs in typhoid fever in man. The patient has recovered from his typhoid, and the physician congratulates him; the next day he is cyanotic, rapid breathing is present, and pneumonia develops: owing to stagnation of the circulation, and the reflow, or pressure, of the blood to the point of least resistance, which is the lungs.

The above tables show that a standard of virulent activity can be produced in cultivations of the swine-plague germs simply by proper nutrition. They further show that not only the selection of material from a natural outbreak can at once provide a preventive virus; but also that, in successive cultivations for generations, this standard can be retained at a greater degree of virulence than other observers claim to have found in natural outbreaks by their controls in rabbits.

Now I must positively, and against every and any assertion to the contrary, assert that I can prevent swine-plague by inoculation. Were I not bound as I am, I would give records of other viruses possessing no virulence whatever, which have produced and still produce an absolutely immune condition in nearly every hog inoculated.

To discover this fact has cost an immense amount of experimentation and a large amount of money. There is one difficulty about it which cannot be overcome. While the virulence of a culture can accurately be tested on small animals, and the exact relation be established between that virulence and a safe dose in the animals in which a given non-recurrent disease occurs naturally, we have no means of testing the preventive properties of a virus, except the results in inoculated animals of the species in which the disease naturally occurs, and this takes a long time and a great many inoculations.

When I began this work, I thought that a test of virulence, with a proper regulation of the proportional dose, was all that was necessary; now I know that a test of virulence with such proportional control is of no value whatever with reference to the protecting power of a given virus. I know this by an experience in over one thousand five hundred hogs. Either one of the six viruses named above will kill a hog by subcutaneous inoculation in sufficient doses, but more reliably by feeding experiments; yet not a single one of them will protect a hog an iota against the cholera; while a germ virus, without any virulence whatever, even by forced feeding, will protect securely and almost invariably, in single doses of one cubic centimeter.

This assertion is obviously contradictory to all previous experiences, and yet, if one stops to think a moment, supported by the most trustworthy experience which we have.

There is no question that, under certain circumstances, using a natural virus, we must reduce the virulence to a certain degree in order to produce a fatal attack by inoculation; but, on the other side, we do not need to have a virus possessing any virulence whatever to produce immunity in a non-recurrent disease.

Vaccination gives the best possible example of the point we desire to call attention to. While in variolation small-pox itself was transmitted, and the variolated person was as much a source of contagion as one having the natural small-pox, the vaccinated individual is absolutely non-dangerous to those coming in relation therewith.

What has been lost?

Certainly something; and the practical evidence conclusively demonstrates that it must have been, or is, that peculiar element of the germ, the contagion, which rendered the variolated person dangerous while the vaccinated one is not.

It is a question of nutrition only, which can be demonstrated by exact experimentation if we only try.

The bovine organism must offer certain nutritive conditions which, in some unknown way, rob the micro-organismal cause of small-pox of its contagious (small-pox) producing qualities, while the preventive one is retained in optima forma.

The same thing can be done with the germ of swine-plague, but to no such degree of absolute certainty as nature or accident has accomplished in vaccina. While it is the easiest possible matter to feed the germ of swine-plague up and down in virulence, to make it extra malignant, or rob it of that quality altogether by changes in the chemical nutrient, it is a most difficult thing to retain the preventive physiological qualities of these germs. Sometimes it can be done for months, and again they are lost in a few generations; but we have no control over these matters except the practical tests. None of the small animals which I have tried can be easily or successfully rendered immune against swine-plague. Rabbits and guinea-pigs can be rendered somewhat immune by repeated inoculations of small quantities of virus; but, so far, I have been unable to render them absolutely so. Pigeons vary; but no more artificial immunity can be produced in them than they naturally have, as will be shown later, and at another time.

As has been repeatedly mentioned, a test or control of virulence has nothing whatever to do with the protective power of a virus. It simply shows that it is safe to use, and that we can establish the point of safety by experiment.

This shows that we have all been working on an erroneous basis. Prevention has no relation to specific virulence. Others have demonstrated the same fact.

In THE TIMES AND REGISTER, Philadelphia, of April 12 and 19, were published a series of most interesting experiments by Chauveau, the most eminent and conservative experimenter in France, in which he demonstrates it in connection with bacillus anthracis. Chauveau says,[1] that "Energetic vaccinal (preventive) properties have been discovered in a pathogenic germ (B. anthracis) not only attenuated in its virulence, but systematically deprived of all infectious properties—rendered so neutral and inactive that we were forced to ask ourselves if this transformed microbe had not become a new species."

"Cultures of bacillus anthracis in this condition can then be carried on in the ordinary atmosphere."

Chauveau conclusively shows that bacillus anthracis produces two chemical elements in its bio-physiological development; the one toxic, or specifically disease-producing, the other having exclusively preventive properties; and that, by cultivation in two to two and one-half pressures of oxygen, the toxic properties may be, or are, lost, while the preventive are retained. Or, to use his own words, "In fact, in my experiments the vaccine property of the transformed bacillus anthracis is so active, and so well survives the loss of all infectious properties, that we seem authorized to consider these two properties as being absolutely independent of each other, and as each belonging to a special product of microbe life."

Another point in evidence of this fact is this: if we take a culture of the germ of swine-plague which has experimentally been shown to actively possess both of these preventive and toxic, or disease-producing, qualities, by actual experimentation, and freeze it solidly for several days, and then inoculate or feed hogs with it, we will find that, while it has retained its toxic, or disease-producing, properties without mitigation, it has entirely lost its preventive property.

That bacillus anthracis has the power of producing these two essentially different chemical elements has also been well shown by Heuppe and Wood.

Though I sometimes criticise the conclusions of my friend Hueppe, still I think him one of the most competent and reliable patho-bacteriologists living, especially in regard to physiologico-chemical attributes of pathogenic bacteria. In the publication mentioned Hueppe and Wood describe a saprophytic bacillus absolutely without virulent qualities, which, in every method of artificial cultivation, or under the microscope, bore such close resemblance to B. anthracis that it could not be distinguished from that organism. It is a well-known fact that all previous experimenters had not been able to render mice immune to anthrax by any system of preventive inoculation; and yet, with this absolutely non-virulent germ, Heuppe and Wood were successful in rendering these most susceptible animals immune to extremely virulent cultures of bacillus anthracis.

Now, it is neither logical nor reasonable to suppose that this was any other micro-organism than bacillus anthracis. It was derived from the earth possessing exactly the attributes described by these observers. In this case the nutritive conditions in the earth had naturally produced exactly the same physiological-chemical conditions in bacillus anthracis which Chauveau has conclusively demonstrated to be possible of production by the cultivation of the same germ under certain degrees of oxygen pressure, and I have been able to do with the swine-plague germ by chemical nutrition, the only difference being that while I have, as it were, "gone it blind," not being a chemist, and accidentally hit on a means of arriving at a certain practical result by innumerable changes in chemical nutrition, until I have empirically arrived at a method of obtaining a certain result for an uncertain length of time, Chauveau has found a definite means of obtaining it with reference to the bacillus anthracis.

That the chemical nutrition method is the one by which practical results will eventually be obtained goes without question; but it remains for the chemist alone to really discover and perfect it.

[1] The original appeared in *Archives Med. Experimentale*, March, 1889.

The discovery of Hueppe and Wood regarding bacillus anthracis finds its confirmation in many diseases of extra-organismal origin, and explains that heretofore mysterious condition known as "acclimatization" in diseases of this character: such as yellow fever, Southern cattle plague, etc. In these cases the specific germs, in a saprophytic or non-malignant condition, must have gained entrance to the individuals possessing this acclimatization immunity while they possessed this prophylactic power, though not possessing the toxic or disease producing.

That all these exogenous germs are, or can be, changed to saprophytic must be self-evident; and that their toxic or disease-producing property is acquired by peculiar nutritive conditions in the soil which they naturally inhabit seems also equally clear. In fact, their acquisition of disease-producing qualities is dependent upon the prolonged saturation of the ground with the excreta of animal life or the decayed products of animal tissues. The delicacy of the action of these germs in different nutritive media is so little understood, and has enjoyed so little experimentation, especially chemical investigation, that we really know very little about it; yet it is the open field of original research which will eventually lead to success, and from which we can only hope for decidedly practical results.

Why the swine plague virus should lose its virulent properties in cattle, or even when cultivated in sterilized cattle urine, is a question no one can decide at present. Why the germ of the corn-fodder disease should not be toxic to animals while still manifesting its presence by specific lesions in green and growing corn, and only become toxic when and after the leaves begin to wither and the chlorophyl suffers chemical changes, are also questions of a nutritive nature which can only be elucidated by the most exact chemical investigations.

At one time in their existence all these organisms are saprophytic, and again they become pathogenically toxic, all of which is determined by the material they develop in.

Before closing, I desire to say a word in relation to fluid cultivating media. When the study of bacteriology first began, these were the only media we had, and it was next to impossible to obtain perfectly pure cultures for the want of a reliable means of isolation. Koch supplied us with this means, but, in doing so, led to an altogether too great neglect of fluid media, which has retarded investigation to a degree not sufficiently estimated by the majority of investigators.

Once it was thought that the only way by which pure cultures could be legitimately attained was by the isolation method offered by the solid media on plates, according to Koch. Now we know that, in the majority of cases, if we inoculate a susceptible animal with material containing a variety of micro-organism derived from an animal having a specific disease, in general, the germ of the latter only will develop; and that, from the specific lesions, we can generally obtain the specific germ in a pure condition if we take the necessary precautions. It is singular that the lesson of this experimental experience has not made more of an impression upon investigators. Why is not the same rule applicable to animals or individuals afflicted with the natural diseases? In other words, why not pathologically decide which is the specific lesion in a given disease, and by experience discover the period in which it is truly specific, and then make cultures directly from it at that time? This point decided, pure fluid cultures can be almost as easily and surely obtained in septicæmic diseases as by recourse to solid media.

In swine-plague, Southern cattle-plague, and the cornstalk disease, all septicæmic in character, I have invariably used fluid cultures in connection with the solid, and with equally successful results as to purity.

The virus No. 1, to which attention has been called, is now in its one hundred and second generation: that is, it has been carried on successfully through about one hundred fluid cultures without one single pollution occurring during all that time. We must resort to fluid cultures if we will be successful in preventive inoculation, for this procedure is one, as well as virulent inoculation, which depends entirely upon the chemical food offered, and only with fluid media can we experiment in that direction or prepare the way for the chemist. Germs which soon lose their virulence on or in solid media retain the same indefinitely in appropriate fluid cultures. Starting with a pure culture, there is no more danger of pollution in the transference from fluid media to the same than in solid media, if one is rapid and dexterous in his manipulations. It is simply a question of strict sterilization and rapid dexterity which gives satisfactory results in either case.

Let me again say that it is only from nutritive experimentation with chemical fluid media that we can arrive at any satisfactory results.

THE REMOVAL OF A DISLOCATED CRYSTALLINE LENS WITH THE AGNEW BIDENT.[1]

By C. B. BLUBAUGH, M.D.,
PARKSBURG, W. VA.

THE crystalline lens, as we know, may be dislocated from disease or violence, or may occur as a congenital condition. It may be only partially dislocated; may swing back and forth, as on a hinge, or may fall entirely back into the vitreous, or be displaced into the anterior chamber; in the latter position it may be extracted by a peripheral corneal cut, though it is best here to use the bident to prevent the lines slipping back through the pupil and into the vitreous. When displaced into the vitreous, we are advised to leave the eye alone, but in following such advice we frequently find, especially in taumatic luxations, that cyclo-choroiditis, hyalitis or detached vetina will ensue, when we are vaguely told to meet these grave complications as the exigencies of the case demand. To remove a dislocated lens from the vitreous, and save the integrity of the eye, is more difficult than any operation in opthalmic surgery, and in describing the bident operation, my best plan will be to cite to you the case which gave birth to the instrument in the fertile brain of the late Dr. C. R. Agnew. It was that of a young man, aged twenty-seven, who had been blind in his right eye from earliest infancy. The form and general appearance of the exterior of the eye were normal, the lens was so loose that it moved to and fro with a quick volatile motion, though suspended on the temporal side by a narrow, hinge-like attachment of the suspensory ligament. Believing that the ordinary methods for the removal of a lens dislocated into the vitreous humor would fail, the procedure which is now offered for consideration was devised. The pupil being first dilated with atropia, the patient was placed on his back and etherized as thoroughly as possible. Wish-

[1] Read before the West Virgina State Medical Society, at Wheeling, W.Va., June, 1890.

ing to have analgesia of the eye, a few drops of a 4 per cent. solution of hydro-chlorate of cocaine were instilled upon the conjunctival surface. The eye-lids were next opened with a Gräfe's speculum and the eye fixed by grasping the tissues between the insertion of the inferior vectus and the margin of the cornea with ordinary fixation forceps. Looking in through the pupil, the dislocated lens could just be discerned lying far to the temporal side of the vitreous chamber in the ciliary region. The bident was now brought into use. It consists of two ordinary, fine, straight, delicately pointed, cataract needles, about six-eighths of an inch long, fixed parallel at a distance a little less than an eighth of an inch apart. These needles are united at their proximal ends by a projection which is flat, and otherwise so shaped and roughened as to be adapted to the grasp of a beak of a holder, such as the Sand's needle-holder. Having mounted the bident in a holder, with the thumb-catch of the latter uppermost, and having the eye-ball firmly fixed, as previously stated, the temporal aspect of the ball was penetrated at a point just far enough to enter the vitreous chamber without wounding the iris or touching the dislocated lens, till the bident had penetrated the vitreous humor to a point a little to the temporal side of its centre, the handle of the holder then being depressed, the points of the bident described an arc forwards, the lens was caught on the bident, as a pea might be lifted on a two-tine fork, and brought forward through the pupil and into the anterior chamber. Then, the bident being pushed on, its points emerged on the nasal side of the eye-ball close behind, but avoiding, the iris. The neat completion of the wound of exit was insured by placing the end of the forefinger of the left hand upon the surface of the eye-ball at the point to which the bident was being directed. In this manner, the scleral conjunctiva being pressed upon the points of the bident, they were passed so quickly through the subconjunctival space, after penetrating the scleratic, as not to let any fluid flow into and distend the subconjunctival connective tissue. The holder was then detached from the bident, and the lens remained free upon its prongs, and pressed against the cornea. A sufficient wound in a downward direction was then made in the cornea, with a narrow Gräfe's knife, and the delivery of the lens easily completed with a delicate wire, or skeleton spoon. The bident was then removed; there was scarcely an appreciable escape of vitreous; the corneal wound fell into neat coaptation and there was no prolapse of iris. The operation was done November 13, and the cure completed December 1.

In my own practice I have had occasion to employ the bident but once. The patient, age forty years, had been struck in the eye with a stone; he was not sent to me for some little time after the accident, when I found the good eye in an irritable condition, and in the injured one the lens was partially in the anterior chamber. I chloroformed the patient, used cocaine locally, and following Dr. Agnew's directions, passed the bident in and pressed the lens into the anterior chamber; made my corneal incision, and with a delicate spoon extracted the lens. Being my first case, I committed the common error of pressing the lens too far forward, thus wedging it in so tightly between the bident behind and the cornea in front that its removal was attended with some little difficulty. I closed both eyes, applying light compresses of absorbent cotton. The second day I removed the dressings and washed the lids thoroughly with a solution of bichloride of mercury, 1 to 2,500, and instilled some in the palpebral slit. I also dropped in the eye a solution of atropia. I pursued this course of treatment, and the recovery of the patient was continuous and uneventful, being discharged cured twelve days after the operation. The modification of the original bident, by Dr. Andrews, of New York, possesses the advantage of having a handle fastened on by a delicate spring, admitting of more nicety of manipulation than where the Sand's needle-holder is used. Some may suggest that the puncture made by the bident in the ciliary region might occasion a sympathetic irritation in the fellow eye; so far this has not been the case and wounds made by the bident have appeared quite unimportant. I am impressed with the idea that where we can detect a fluid vitreous in ordinary cataract extraction, the bident would be of decided advantage in preventing loss of vitreous.

The Polyclinic.

PHILADELPHIA HOSPITAL.

ERNEST LAPLACE, M.D.

METASTATIC EPITHELIOMA.

THE woman who will be brought before you for operation is suffering from metastasis resulting from an epithelioma of the lip. She was operated upon last year, for epithelioma of the lip, and at that time no infiltration of the glands could be detected; but, after the operation, a new cancerous focus was established in the glands of the neck.

By an epithelioma we understand a growth that starts from epithelium. We call the lining membrane of the skin and mucous membrane epithelium. There is another set of cells that resemble epithelium—that grow, as epithelium does, by karyokinesis—and are not found over the surface, but within certain structures, and, in place of being called *epi*-thelium, are called *endo*-thelium. Epithelial cells are flattened, and consist of a nucleus with a mass of protoplasm around it. Any tumor that starts from the epithelium is an epithelioma.

On the other hand, I spoke of another group of cells that is found, not upon the skin and mucous membrane, but in the vessels and glands, and called endothelium. These two kinds of cells, aside from shape and size, proliferate by a splitting up of their nucleus. The nucleus grows larger and contracts in the center into an hour-glass form, and then divides into two parts or nuclei, and the cell then splits into two distinct cells. When all the cells of a part have repeatedly undergone this change we have an epithelioma.

There is a whole mass of glands on the right side of this woman's neck, which are enlarged. An incision is made along the line of the glands, and the mass is found to be very friable. First of all, circumscribe the tumor, and it is an easy matter to attend to the rest. I find this mass to be connected with the masseter muscle, and it is also necessary to denude the maxillary bone. It is almost impossible to avoid cutting the facial artery, and precautions must be taken to see that it is properly ligated. The wound is thoroughly cleansed with antiseptic solution, and ligatures applied after the wound has been painted with a solution of iodoform and ether. Dress antiseptically.

In this case we must be ready for every emergency, for we are working in a very delicate region. A tampon applied for a few moments will stop all oozing

effectually. There is not the slightest objection to applying a sterilized ligature around a vein or artery, and allowing it to remain in the wound. Formerly, bad results from the use of the ligature came from the introduction of germs and septic matter. At present we ligate every important vein and artery without fear. Should we not be able to stop the hemorrhage without a ligature, what should be done? If the patient could not afford to lose any blood, put on the hæmostatic forceps, and allow them to remain for twenty-four hours, and this will check it, with a good deep suture. In this case there is no necessity for this procedure.

In every case where we have used a ten per cent. solution of iodoform and ether after the operation, we have not had a single drop of suppuration.

THE FUNDAMENTAL FACTORS IN THE CAUSATION OF THE INFECTIOUS DISEASES.—1. All toxicogenic germs are dangerous when introduced into the body.

2. Filth may and does breed disease.

3. It is not necessary that milk should contain a specific germ in order to poison a child, or that water should contain Eberth's bacillus in order that it may induce typhoid fever.

4. Wheresoever man builds for himself a habitation and poisons the soil about him and the water which he drinks, with his own excretions, there will be enteric fever.

5. A good digestion and a healthy gastric juice does aid in the prevention of disease.

6. We can still continue to treat consumption by good, generous feeding and constitutional treatment, without the risk of being denounced old fogyish and unscientific in our practice. Such practice is more scientific and more successful than such fads as the rectal administration of hydrogen sulphide gas and inhalation of hot air, which have been imported in recent days from France and Germany.

Our fathers who treated tuberculosis with cod-liver oil and recommended out-door exercise, but who carried no gas bags and knew nothing of the Weigert oven, were not such fools after all.

In conclusion let us state that the germ is only one of the factors in the causation of the infectious diseases. The other factors are to be found in disordered digestion and impoverished blood.

—Vaughan, in *Med. Age.*

TREATMENT OF DIPHTHERIA.—The author has treated in the past two years two hundred and eighty cases of undoubted diphtheria. Six of these cases were complicated with laryngeal diphtheria, and fourteen with nasal diphtheria; about twenty cases were of the severest type, and 45 per cent. of all the cases were below the age of ten years. The treatment consisted of the administration internally of $\frac{1}{10}$ to $\frac{3}{10}$ per cent. solution of thymol, and sometimes also of arac or cognac.

The action of the remedy was rapid, especially in overcoming the tendency to general systemic poisoning. It was given at short intervals (usually five minutes) in doses of five or six drops. In primary laryngeal croup this remedy has three times been successful.

No unpleasant results were at any time observed.

—Gros, trans. in *Annals Gyn. and Pæd.*

ALTERATIVES IN NERVOUS DISEASES.—Each year of my special practice in diseases of the nervous system, I grow more and more convinced that too much stress is placed upon the use of tonics and stimulants therein, and too little reliance upon drugs intended to change blood. There is a distinct limit to the former, for they rapidly lose effect if continued any great length of time, and their number, although large, is not sufficient to keep up a non-ending relay. It is curious how soon toleration of any one of this class of remedies is established up to immense doses, and how long it is before the system recovers so that small ones will have the primary effect. I have a patient upon whom a less dose of compound elixir of cinchona than four ounces is useless, and who only feels that dose pleasantly. Every practitioner has had similar experiences, and has gone through the gamut of tonics only to turn in disgust from the shelf that holds them, in despair of finding something new.

It is in the hope of supplying this need that I wish to call attention to some of my own work in the line of nervous diseases, in which I am interested.

About two years ago, a young lady came from central Maine to me, suffering with an obscure disease of the spinal chord, which had prostrated her nervous system, and made of a strong girl an apparently hopeless invalid. For months she had been unable to help herself from exhaustion, all functions were disturbed, and melancholia threatened.

After a few days' rest, I began the use of central galvanism systematically, and continued it for ten days. At the end of this time, in place of improvement, there was positive loss. She was weaker than at first, and it became evident that something else was called for.

She was then placed in an isolated quiet room, with a trained nurse, and fed with my favorite mixture of equal parts of cream and Valentine's beef juice, a teaspoonful every half hour. At the same time I commenced the administration of iodine, using by preference Gardner's syrup of hydriodic acid in ten-drop doses hourly. I find that this preparation is by far the best form of iodine for rapid dosing, as it is pleasant to taste and rarely, if ever, produces coryza.

In three days the girl showed improvement, and in three more was so much better that seclusion was abandoned and the dietary enlarged to take in some solid food. The iodine was continued in drachm doses of the same syrup four times daily for another week, when Miss B. was on the high road to cure, and had commenced to taste metal plainly.

The iodine was then exchanged for hypophosphates, a half ounce at bedtime. Contrary to usual belief, I find this the most effective way of using this drug. There is a more rapid absorption going on during sleep than in waking hours, and the nervous system is more susceptible to influences of all kinds.

At the end of three weeks of the hypophosphates, accompanied by a diet list of usual proportions, Miss B. was sufficiently well to be permitted to return home, and has since remained in fair health.

The preparation last used was also from the Gardner laboratory, and I am convinced that it is essential to have these compounds pure, a condition that does not exist in every formula on the market.

I have had a bottle of each of these remedies of this make on a shelf in my medicine closet for six months without their undergoing any change, either in color, taste or therapeutical properties, and can recommend them as reliable.

All nervous diseases are either accompanied by, or are the result of, blood change, and will be most successfully treated by such means as will tend to restore the blood to a normal condition, and in my experience these have proven to be alteratives.

—Hutchinson, in *New Engl. Med. Monthly.*

IRREGULARS.

THE relations of the irregular schools to the medical profession are attracting considerable attention. In an editorial on Eclecticism, the *Medical Record* discusses the attitude of this sect, and concludes that there is no place for such a special school. Nevertheless, there are in this body practitioners who have the confidence of their fellow-citizens; there are men who have received a thorough medical education; and they have shown the estimation in which they are held by procuring in New York legislation putting them on an equality with the vastly more numerous members of the regular profession. With colleges conducted by educated men, requiring, in one case, a graded course of three years, covering substantially the same ground as the regular colleges, many will ask why eclecticism exists. The sect no longer limits its therapy to the vegetable kingdom; but claims as broad a field for choice as we do. Recognizing that in the regular profession there is the utmost liberty for individual preference, why cannot these men find within our folds all the opportunities they need, without keeping up a separate establishment?

The reason lies in this, that they cannot get into the regular fold, and that the body of their sect—not the head that gives respectability to it, but the great mass—is not so well qualified as to be admitted. The young man who has, unwittingly, entered an eclectic college, has no other resource but to remain an eclectic for life, live in professional isolation, or spend three years in a regular medical college. This is practically a prohibitory tariff; he is a sinner past redemption. To a great many, the three years would be well spent; as their previous collegiate course was of flimsy texture. But here and there we meet with one who does not need such a course; and to whom its exaction would be the waste of a larger section of one's life than any good man can afford to waste. For these it is an injustice to require it. We have already stated our belief that if our doors were opened to this class, there would be an end of eclecticism as a separate school. The truth of this is shown by the uneasiness it has occasioned among eclectics to whom it does not apply. One eclectic journal raises the cry of alarm over it, and loudly demands the upholding of sectarianism. Our memory is not so short but that we recollect seeing the name of that journal's editor upon the list of Buchanan's graduates. It is quite natural he should oppose any movement which would withdraw the worthy eclectics from their unworthy associates.

Give these men a chance to rectify an error into which they fell at a time when they had not acquired such a knowledge of medicine as enabled them to choose wisely. How well qualified is any of our own students to judge when he first enters upon his studies? Did any one of our readers enter the regular profession after a careful examination of its principles and a comparison with the other schools? We have yet to meet the physician who did anything of the sort. We became regulars because our family doctors or preceptors were regulars; or because the university we attended as under graduates had a regular medical department. Why, then, so relentlessly visit upon others the consequences of a choice no more thoughtless than our own? Our proposition is simply this: That the American Medical Association should authorize the colleges to admit to the graduating class practitioners of other schools who have taken complete courses of medical study, and are able to pass the examinations required of our own second course students. It is to be understood that this privilege is to be extended only to those who shall signify their intention to practice medicine regularly, in accordance with the code of ethics of the Association.

Letters to the Editor.

SCREW-WORMS.

CASE I.—In August, 1882, in one of the wards of our County Hospital, I found a man who had been admitted for break-bone fever, contracted in the southern part of Arkansas, from which place he had just arrived.

He told me that he had that morning spit up several worms, which he had preserved to show me. They were screw-worms about three-quarters of an inch long and one-quarter of an inch in diameter. Upon examination, I found the mucous membrane covering the roof of the mouth thickly studded with black dots, which were moving. Applying the forceps, each dot proved to be the head of a screw-worm, and in a short time twenty were removed. Upon further examination they were also found in the nasal cavity, filling both nostrils. I injected a spray of chloroform, and then adjusted a post-nasal douche, using carbolized water, which brought away quite a large number. Ordered douche continued, also a spray to the nasal, post-nasal and pharyngeal walls, which had the effect of removing all within four or five days. During the treatment he called my attention to a small swelling, just anterior to the sterno cleido mastoid muscle, and about an inch below the angle of the inferior maxillary, and said that he thought it contained worms, for he could feel their movements. Upon examination I became convinced that his suspicions were correct, and cutting down upon them, eight or ten were removed, that had evidently bored

their way through the soft tissues of the throat to that situation. After thoroughly disinfecting the cavity, or nest, in which they were found, no further trouble was experienced.

CASE II.—On the 23d of July, 1890, I was called to see Mary Welch, an orphan girl, aged seventeen years, living in a railroad camp, and who was said to be suffering from neuralgia. The right side of her face was very much swollen, eye closed, and suffering intense pain. There was also a very offensive discharge from the right nostril. Upon close examination, with the speculum, to find the cause of the discharge, I was surprised to find a living, moving mass of worms entirely filling the nasal cavity of that side. Ten or twelve were removed with long dressing forceps. I next used a douche of carbolic acid 1 to 1,000, which brought away a few more. Upon examining the mouth I found the pharynx, tonsils, and roof of mouth filled with them, but all under the mucous membrane, where I could not get at them. I saw her once a day, and after removing all worms in sight with forceps, the entire nasal cavity was disinfected by the carbolic acid solution, and then dusted over with iodoform. This treatment had the effect of driving them into the nostrils and into the mouth, and from there they were blown out, or spit out, or removed by forceps.

Treatment was continued four days, removing fifty-seven worms in all, after which patient made a good recovery.

This worm, called the screw-worm, or Texas borer, is from one-half to three-quarters of an inch long and one-quarter of an inch in diameter, pointed on both ends. It is very active in its movements, and the ability displayed in boring into and through the soft tissues of the post-nasal region is marvelous. The body is made up of successive layers or rings, very much resembling a screw, hence their name.

They are the product of the egg of the Texas fly, and are extremely rare in this part of the country, but three cases having come to my knowledge in the past twenty years. It is supposed that the egg is deposited by the fly in the nostril during sleep, from which the worm is developed. This theory is very well supported by my two cases, the one sleeping out doors a great deal, and the other living in an open tent day and night. E. W. FIEGENBAUM, M.D.

EVANSVILLE, ILL.

CORRECTION.

ON page 157 of your journal, you do this institution a great injustice, as no one has "died in the insane department of the Philadelphia Hospital, from scalds accidentally received while bathing." The accident was at another hospital. Will you kindly correct the statement? D. E. HUGHES, M. D.

[The substitution of the definite article for the indefinite was overlooked by the proof-reader, which occasioned the mistake.]

Book Notices.

CYCLOPEDIA OF THE DISEASE OF CHILDREN, Vol. III. Edited by JNO. M. KEATING, M.D. J. B. Lippincott Company.

The third and largest volume of Dr. Keating's great work does not suffer in the least by comparison with the two which preceded it. The scope and magnitude of the Cyclopedia are in themselves conclusive evidence of the fact that the subject "Diseases of Children," is not to be looked upon as a specialty—the limits of its boundary lines being altogether too wide. In the space at my disposal it is impossible to review even briefly all the articles of the volume—a totality of forty-seven. A mere enumeration of them, or, at most, a few general statements must suffice for the majority of the papers, while a small number seem to demand somewhat more elaborate mention.

The subjects discussed are, with a few exceptions, of great practical importance, and were, for the most part, treated with due thoroughness by well-known authorities, some of whom are specialists, handling familiar subjects in their respective domains.

A few of the articles have little more than a scientific interest for the medical practitioner, but this is manifestly unavoidable in a work whose purpose is to convey encyclopedic knowledge. On comparing the illustrations of the present volume with those of Vols. I and II, we find them to be more numerous and, on the whole, superior. The plates of Holt, showing hyperplasia of lymph-nodules, superficial and deep ulcers of colon, acute and chronic catarrhal and croupus inflammations of the small and large intestines, being especially fine. There are about two hundred and fifty figures contained in the present volume, all of which are creditable. We have but a single criticism to offer, and this would apply to all works of similar pretensions, viz., too great division of labor has in many places throughout the book caused needless and excessive repetitions.

In Part I are discussed "Diseases of the Digestive System," and it contains, among others, the following articles: Functional Diseases of the Stomach, by Dr. Wm. Pepper; The Diarrhœal Diseases, Acute and Chronic, by L. Emmett Holt, M.D; Intestinal Bacteria of Children, by Wm. D. Booker, M.D.; Tabes Mesenterica, by A. Jacobi, M.D.; Enlargements of the Liver, by J. H. Musser, M.D.; Contractions of the Liver, by Marcus P. Halfield, M.D.; and Intestinal Obstruction in Children, by W. W. Keen, M.D.

Dr. Pepper's opening paper has the great merit of being practical. We doubt the propriety, however, of describing cyclical vomiting as a distinct condition, since it invariably is merely symtomatic of a great variety of disturbing causes. The excellent article on the Diarrhœa Diseases by Dr. Holt deserves to be widely read, as does also that by Dr. Booker on the Intestinal Bacteria, a subject which is engrossing, and, on account of its practical bearings, deservedly so, a large share of professional attention.

Dr. Musser's discussion of the various conditions and diseases which cause enlargement of the liver is clear and full. This is especially true of the author's treatment of abscess of the liver.

Part II is devoted to "Diseases of the Genito-urinary Organs," and contains not less than thirteen articles. Dr. John F. Goodhart has an excellent paper on "Acute and Chronic Bright's Disease." The author emphasizes the facts that the onset of parenchymatous nephritis may be very insidious, and that "for the diagnosis in such cases thirst may be the guiding light." There is no more praiseworthy article in the whole volume than that by Dr. De Forest Willard on "Malformations of the Penis, Urethra, and Bladder." Every practitioner will readily agree with this writer in stating that "a degree of deformity which would be simply an annoyance, if situated on some other portion of the body, becomes, when associated with the genitalia, so mind-absorbing,

that the individual is rendered morbidly sensitive, and at times becomes almost a sexual monomaniac."

The surgical procedures for the permanent relief of many of these defects are clearly described by one who is, verily, master of his subject. There is a capital chapter on "Diseases of the Blood," by J. P. Crozier Griffith, though it should have found a place in another volume.

Part III—*Surgery*—opens with a worthy introduction by Chas. W. Dulles, M.D., on "Minor Surgery and Emergencies in Children." That portion of the article which deals with emergencies is of great practical value to the practitioner, and especially the author's table, giving the names of most mineral and vegetable poisons and the proper treatment of each.

The subject of "Anæsthesia and Anæsthetics" is ably presented by Dr. O. H. Allis, although it is with great regret we note that his "decided preference in every case, and especially for children, is for that anæsthetic" (chloroform), the author believing this agent to be perfectly safe when rightly administered.

Dr. Thomas R. Neilson introduces Part II (Diseases of the Osseous System and of the Joints) by a good presentation of the subject: "Congenital Abnormalities of the Extremities."

"Club Foot" and "Torticollis" are treated in a satisfactory manner by Drs. E. H. Bradford and E. G. Brackett, and "Fractures and Dislocations," by Dr. J. H. Packard, well-known surgical writers. The last chapter is closed with an article from the pen of Dr. Wm. Barton Hopkins, who discourses learnedly on the subject of "Amputations."

There is certainly much remaining that should be favorably mentioned in the present volume, did space permit; in short, this admirable work should, as it doubtless will, find a place in the library of every truly progressive physician. J. M. A.

Pamphlets.

The Application of Vocal Culture to the Treatment of Throat and Pulmonary Affections. By Eugene L. Crutchfield, M.D., Baltimore, Md. Reprint from *Gaillard's Medical Journal*, August, 1890.

The Medical Digest.

ARNAUDET has made an important contribution towards the study of cancer, as to its contagiousness. He finds that in a Normandy village ratio of deaths from cancer is four times that of Paris. The drinking water is largely drawn from surface ponds, and this is used in the manufacture of cider. The malady developed successively on a line corresponding to the water-supply of these ponds. Such studies could be made in many cases by country doctors.

IS DIABETES CONTAGIOUS?—Schmitz asks the question (*Berlin Klin. Wochensch*), struck by the large number of cases to be found at a thermal station frequented by diabetics. Women in apparent health are often seized suddenly with diabetes, while they are caring for diabetic husbands; even when no heredity can be traced, and no special cause exists. In one case a woman of healthy antecedents married a diabetic. Shortly after his death she was found to be herself affected with glycosuria; but, marrying again, her second husband was soon attacked with diabetes.

—Cozzolina, in *Prov. Med. Jour.*

CALOMEL AS A DIURETIC.—From the reports thus far presented, we may safely conclude that:

1. Calomel, and in all probability other mercurial compounds, possess diuretic properties.

2. If given in proper dose, the effect of calomel becomes evident in two to ten days. Continuance of the treatment during the diuresis will not alter or increase the effect.

3. Its action is most marked in dropsies due to heart disease. Its action in dropsies of hepatic origin is not to be relied upon. Pathological changes in the kidney prevent or abridge its action.

4. Small doses will prove of no avail.

5. The diuretic action may, in all probability, be ascribed to the irritating effect which the mercury, during its elimination, exercises upon the renal epithelium.—Fackler, in *Jour. Amer. Med. Asso.*

LIPPINCOTT contributes to the *American Journal of Ophthalmology* a paper upon intraocular syringing in cataract extraction, with a report of fifty-three operations. He draws the following conclusions:

"1. The absence, excepting in one case (No. 41), of inflammation or irritation directly referable to the operation, and the absence, also excepting in one case (No. 30), of inflammation from any source serious enough to cause anxiety.

"2. The large proportion of cases in which a high degree of visual acuity was obtained.

"3. The large proportion of cases in which the operation was surgically complete, *i.e.*, in which no capsular opacity remained to be treated by secondary operation. (I make no note of the absence of suppurative inflammation because purulent processes, as remarked by Sattler, Knapp, and others, are of late becoming more and more rare.)

"These advantages I cannot but think attributable in a large degree to the fact of the anterior chamber being so thoroughly cleared of residual cortex."

Speaking of the syringe utilized in these cases he says:

"1. As there is no backward flow, it (the syringe) has no tendency to become septic in use except at the point of the nozzle, and the latter can be readily pulled off and thrown into boiling water or alcohol. If the purity of the other parts of the apparatus is suspected, it is easy to place the reservoir in boiling water, and to replace the old rubber tubing with a new piece.

"2. This instrument can always be depended upon to work smoothly.

"3. It is held like a penholder, and is as easily and securely handled.

"4. As the ejecting force is proportional to the height of the column of liquid, it is of course under absolute control. . . .

"Should a *per saltum* movement be desired, this can be effected . . . by intermittent pressure on the short piston.

"5. It goes without saying that in using this syringe there is no possibility of the entrance of air into the eye."

Medical News and Miscellany.

THE next Congress will be held at Rome, in 1893.

DRUNKENNESS is said to be largely increasing in France.

DETROIT doctors are quarreling over their ability to kill diphtheria germs.

DR. N. SAXMAN, of St. Mary's Hospital, is at Brighton Beach, recuperating.

HEBREW women are almost universally sufferers from uterine and vaginal maladies.

THERE were 355 children sent out last week by the Children's Country Week Association.

DR. GEORGE T. ENGLISH is one of the most popular guests at the Prexton Villa, Cape May.

DR. J. DALLAS ERDMAN, of Macungle, has had his property seized by the Sheriff on an execution.

THE Canadian Medical Association will hold its annual meeting in Toronto, September 9, 10, and 11.

SURGEON-GENERAL JOHN MOORE has been placed on the retired list, by operation of law, on account of age.

IT is stated that small-pox is causing many deaths in the ranks of the Guatemalan army on the Salvadorian frontier.

GRANDON MACREADY, a sixteen-months-old child, was burned with carbolic acid last week, but is reported as improving.

MRS. TILLIE BROWN, at the point of a pistol, rescued a little girl from the hands of a ruffian at Brown's Mills, N. J., last week.

A BERLIN man, bent on self-destruction, found a new way out. He drank a quart bottle of copying ink and blotted out his existence.

NORMAN KERR pronounces hypnotism to be in ninety-nine cases out of a hundred, therapeutically useless and morally dangerous.

DR. J. M. DACOSTA, who was recently the guest of of Mr. and Mrs. George W. Childs, at Elberon, N. J., is now sojourning at Bar Harbor.

M. FILLET DE GRANDMONT has succeeded in restoring the eyelids of a child, by grafts of frogs' skin. The lids had been destroyed by a burn.

PROF. R. VIRCHOW will be three-score and ten years old on October 13. It is proposed to make the event memorable by a banquet and celebration.

DR. G. MILTON BRADFIELD, recorder of the Medical Jurisprudence Society, has lately returned from a trip to Boston, Newport, and Narragansett Pier.

THE Citizens' Passenger Railway Company's stables were destroyed by a severe storm in Philadelphia last week. Six people were killed, and seven injured.

GERMAIN SÈE recommends cannabis Indica for gastric pain. He gives gr. ⅓ of the extract at a dose. This relieves pain, heartburn or epigastric discomfort, without interfering with digestion. The usual treatment, dietetic and medicinal, should also be directed against the causal disease.

THE Trustees of the Camden Methodist Home for the Aged and Infirm have resolved to erect a large home building at Collingswood.

A PHYSICIAN should never idle away his time all day in his office. It's poor practice.

—*Binghamton Leader.*

AN old Indian mound was opened, lately, near Virginia, Ill. It is two hundred feet in length at the base, and one hundred feet broad, by thirty feet in height.

SURGEON WYMAN, of Washington, last week replied to Chief Clerk William P. Troth in relation to the report that yellow fever existed at Port Simon, Costa Rica.

THE threatened legal contest between the Medico-Chirurgical Hospital trustees and adjacent property owners has been amicably settled, both sides making concessions.

A STORY comes from Parkersburg, W. Va., of a snake eight feet long becoming the pet of a family. The said snake answers to his name when called, so the story goes.

THE Senate has agreed to the House amendments to the bill providing for the inspection of meats for exportation. The measure now goes to the President for his signature.

THE new management of the Atlanta *Medical Journal* says it will remove advertisements from among the reading pages. Would that all medical journals would do likewise.

BELLEVUE HOSPITAL MEDICAL COLLEGE and the University Medical College, N. Y., beginning next year, will each require three courses of lectures for graduation. Good.

THE Czar of Russia, it is reported, now employs an American dentist exclusively. And, considering how constantly the Nihilist keeps his teeth on edge, the dentist has no sinecure.

QUITE a sensation has been created in London by the discovery of a case of Asiatic cholera; the patient landed from the steamer Duke of Argyll, which had just returned from Calcutta.

DR. J. H. DOUGLAS, who attended General Grant during his last sickness, has been seized with paralysis, and lies helpless and poverty-stricken at the Presbyterian Hospital, New York.

THE favorite wife of the Shah has been operated upon by Vienna oculists for glaucoma. It is said the consulting Persian physicians who recommended the operation are confined to await the result.

WILLIAM HANLON, one of the famous Hanlon Brothers, had a severe fall from a trapeze in the New York Academy of Music, last week. Drs. Gray and Hallock, of the New York Hospital, attended him.

DR. J. ORNE GREEN says that he has operated upon seventy-eight cases of meningitis from disease of the middle ear. Of these, sixty were cured, three not cured, seven died, two unknown, six unfinished.

A NEW monthly medical journal was issued August 15, at Asheville, N. C., called the *Asheville Medical Review*. Frank T. Merriwether, M. D., and H. Longstreet Taylor, A. M., M. D., are the editors and publishers.

An epidemic of diphtheria, of the most malignant type, is reported from Chicago, in that portion of the Town of Lake known as "the New City." The section is said to be in bad sanitary condition.

The Marine Hospital Bureau has been notified of a case of yellow fever on board the Spanish bark Castillo from Cienfuegos via Pencougala, now detained at the Chandeleur Quarantine Station, Mississippi.

Officials of the Chicago Infirmary have discovered that bodies of paupers buried in the lot belonging to the institution have been disinterred and sold to medical schools for dissection, and that the business has been carried on for a long time.

The announcement was made that twenty car loads, or 20,000 watermelons, from Charlestown, Mo., were to be auctioned in New York last Monday, and it is believed that speculators with a car load of paregoric were in pursuit of the train load of bombs.

Mayor Fitler last week sent the balance of the fund for the entertainment of the Pan-American Congress, amounting to $204.22, to the Southern Home for Friendless Children. This was done after the wishes of the subscribers to the fund had been consulted. The total amount of the fund was $3,900.

Dr. William Rice last week filed his statement in the case against the Philadelphia *Inquirer* to recover $10,000 damages on account of a publication made in the *Inquirer* on November 13 last and circulated. Dr. Rice alleges that the charges made in the article are untrue, and the publicity given them by the paper has seriously injured his good name, fame, and reputation.

Chicago Polyclinic. — The following appointments have been made: Drs. G. Fütterer, F. C. Hotz, and E. Fletcher Ingals, Professors of Internal Medicine, Ophthalmology, and Laryngology, respectively. Drs. Chas. F. Stillman, P. S. Hayes, and J. M. Patton, Associate Professors of Orthopædic Surgery, Electro-Therapeutics, and Medicine, respectively.

London, Aug. 15.—The Government of India reports that the medical authorities are unable to agree as to whether leprosy is contagious or not. The local governments also differ on the question. The proposed legislation will therefore be postponed until full details have been collected through the National Leprosy Fund in conjunction with a medical commission, which will leave England in October.

The Coroner's jury in the case of Frederick Schroeder, who was thought to have been murdered by James Hall, at Morrisville, this State, last Monday week, concluded its testimony, and returned a verdict that Schroeder died from paralysis of the heart. The most important testimony was that of Dr. William E. Case, of Morrisville; Dr. George H. Stroup, of Eddington, and Dr. A. S. Wilson, of Bristol.

The annual meeting of the American Social Science Association will be held in Saratoga in the week beginning September 1. Several Philadelphians belong and will attend the sessions. Dr. H. L. Wayland reads a paper on Laissez-faire Run Mad, and Dr. W. B. Atkinson, Secretary of the Pennsylvania State Medical Association, will talk about Infants and Children and Their Food. Most of the economists of the country will be in attendance; Profs. James and Thompson, of the University, among them.

Dr. Albert Shaw, who recently contributed a striking article on Glassgow in *The Century*, is to write a series of papers for that magazine during the coming year, on "Municipal Government in Europe and America."

A Detroit man who drank a quart of embalming fluid in mistake for liquor, became as rigid and as white as marble half an hour before death, and when death came finally he looked more like a mummy than a corpse.

Dr. Simon N. Patten, Professor of Political Economy at the University of Pennsylvania, has been gathering vigor abroad this summer. At last accounts he was in Switzerland, and writes that he has bought a pair of seven-pound hop-nailed shoes for tramping over the Alps.

A boy cured of a dislocated neck is the prize case of the Presbyterian Hospital. The patient is so well mended that he does not have to wear a support to hold his head up. There have been broken necks mended, but few, if any, so well as this. The patient is Harry Reigel, fourteen years old, 511 North Forty-first street. He was attended by Dr. De Forrest Willard and Dr. Wm. C. Posey, a rising young physician.

From Tuesday to Thursday, it is reported there were twenty-eight deaths from cholera and forty-eight fresh cases of the disease at Eltor, in Egypt.

The dreaded disease seems to be steadily spreading along the Mediterranean coast of Spain, as well as into the interior of New Castile, where both Madrid and Toledo are more or less infected. Persistent rumors come of its appearance in the South of France, all of which, however, are denied vigorously, and the authorities are now watching suspicious cases at Liebenwalde, near Berlin.

The increasing popularity of the idea of the revival of the apprenticeship system received a curious illustration in the suggestion made by Mr. Lawson Tait, President of the Mason College, Birmingham, before the meeting of the Medical Congress. In considering the training essential for the craft of surgery the speaker cordially recommended the restoration of the apprenticeship system for medical and surgical students. He believed that an art like surgery cannot be acquired by passing examinations, but that other qualities are needed by the surgeon than simply knowledge derived through books and the training of schools.

The Anglo-American Dinner.—One of the social incidents at the Berlin Congress was the Anglo-American dinner, given by a few hospitably disposed Englishmen and Americans to friends of both nations at the Kaiserhof Hotel, on Friday last, with Dr. J. V. Shoemaker, the well-known therapeutist, of Philadelphia, in the chair. Upward of sixty representative medical men were present, including Dr. Landolt, of Paris; Profs. Pancoast and Goodman, Philadelphia; Dr. Wm. Murrell, London; Prof. Leech, Manchester; Dr. Parkes, U.S.A., etc., and in addition, the editor of the German *Pharmaceutical Times;* Mr. Burroughs, London; Mr. Evans, Philadelphia, and other well-known pharmacists were present. Although the arrangements were seriously interfered with by the delay entailed by the return of many of the guests from the Imperial reception at Potsdam, a thoroughly agreeable evening was spent by the company, most of whom only meet triennially on the occasion of these congresses.—*Med. Press.*

NEW PATENTS :—

PATENTS GRANTED AUGUST 19, 1890.

Dental Engine.....A. W. Browne.....Prince's Bay, N. Y.
Hand-Piece Pulley-Head for Dental Engines.....A. W. Browne.....,Prince's Bay, N. Y.
Dentist's Mixing-Slab.....L. Teal.....Philadelphia, Pa.
Blue Die.....A. Weinberg.....Frankfort-on-the-Main, Germany.
Lotion.....F. Schmidt.....Brooklyn, N. Y.

TRADE-MARKS ISSUED AUGUST 19, 1890.

Bitters (The word "Sioux")..E. Lassig Co.....Goodwin, S. D.
Perfumery, toilet-waters, soap, sachet-powders and smelling-salts (The word "Opal").Ladd & Coffin.....New York, N. Y.
Tooth-powder (The word "Ambrosial").....F. A. Ewer.....New York, N. Y.
Antibacterials, aseptics, and antiseptics, and antizymotics (The word "Pyoktanin").....E. Merck.....New York, N. Y.
Toilet lotions (The words "Diaphanous, Antephelis, Antiwrinkle Lotion").....M. J. Pinoult..... Boston, Mass.
Hair-restorative (The word "Champion" and a portrait of Mary M. Snyder).....M. M. Snyder & Co.Creston, West Va.
Liniment (The word "Magic," with two circles surmounted by an American eagle).....L. Conrad.....Elizabeth, N. J.
Mineral water (The word "Nee-Ska-Rae").....Nee-Ska-Rae Mineral Spring Co.....Milwaukee, Wis.

LABELS REGISTERED AUGUST 19, 1890.

"Marshmallow Cream".....The Diamond Laboratory Co.....Naugatuck, Conn.
"Youngkin Brothers Screw-Worm Exterminator".....J. A. and J S.Youngkin.....Sweet Home, Tex.

—Charles J. Gooch, *Patent Attorney.*
LOCK BOX 76, WASHINGTON, D. C.

THE Government physicians, of Madrid, have announced their refusal to serve any longer in the cholera infected districts unless they are given a strong military escort. They declare that the peasants are opposing all attempts to institute sanitary precautions, and even resort to force in order to prevent them from doing their duty, and that under these circumstances any abatement in the virulence of the disease is quite impossible. The city of Argos has been deserted by all the inhabitants, only those who are down with the cholera and a few relatives who refuse to desert them being left.

THE trustees of the Helen Prideaux Memorial Fund have awarded the prize to Miss Adela McCulloch Knight, M.B. Lond., the Australian lady now Resident Medical Officer at the New Hospital for Women, Euston Road, who studied at the London School of Medicine for Women.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 28, 1890, to August 23, 1890.

By direction of the Acting Secretary of War, leave of absence for one month and fifteen days, to take effect about August 15, 1890, is granted Major Daniel G. Caldwell, Surgeon. S. O. 176, par. 1, A. G. O., July 30, 1890, Washington, D. C.

By direction of the Acting Secretary of War, Captain William Stephenson, Assistant-Surgeon, now on duty at Columbus Barracks, Ohio, is assigned to temporary duty at Jefferson Barracks, Missouri, during the absence on leave of Daniel G. Caldwell, Surgeon, and will report accordingly. On the return to duty of Major Caldwell, Captain Stephenson will rejoin his proper station. S. O. 176, par. 2, A. G. O., July 30, 1890, Washington, D. C.

PROMOTION.

To be Assistant-Surgeon, with the rank of Captain after five years' service, in accordance with the act of June 23, 1874: Assistant-Surgeon Francis J. Ives, July 25, 1890. Headquarters of the Army, A. G. O., Washington, August 11, 1890.

To be Assistant-Surgeon, with rank of Captain after five years' service, from August 12, 1890, First Lieutenant and Assistant-Surgeon Wm. P. Kendall. Headquarters of the Army, A. G. O., Washington, August 18, 1890.

The leave of absence for seven days granted Captain George McCreary, Assistant-Surgeon, by Orders No. 84, Fort Warren, Mass, August 13, 1890, is hereby extended fifteen days. S. O. 193, Headquarters Division of the Atlantic, Governor's Island, New York City, August 15, 1890.

By direction of the Acting Secretary of War, the retirement from active service, this date, by operation of law, of Brigadier-General John Moore, Surgeon-General, U. S. Army, under the provisions of the Act of Congress approved June 30, 1882, is announced. General Moore will repair to his home, Bloomington, Indiana. S. O. 191, par. 2, A. G. O., Washington, D. C., August 16, 1890.

By direction of the Acting Secretary of War, First Lieutenant Charles F. Mason, Assistant-Surgeon, is relieved from further temporary duty at Fort Logan, Colorado, and will report for duty at his proper station (Fort Washakie, Wyoming). S. O. 191, par. 3, A. G. O., Washington, D. C., August 16, 1890.

By direction of the Acting Secretary of War, a board of medical officers, to consist of Major Joseph V. D. Middleton, Surgeon; Major Clarence Ewen, Surgeon; Captain William E. Hopkins, Assistant-Surgeon, will assemble at the U. S. Military Academy, West Point, New York, at 11 o'clock, A.M., August 27, 1890, or as soon thereafter as practicable, to examine into the physical qualifications of the candidates for admission to the Academy. S. O. 192, par. 1, Washington, D.C., A. G. O., August 18, 1890.

With the approval of the Acting Secretary of War, leave of absence for four months, to take effect about September 1, 1890, is granted Captain Walter Reed, Assistant-Surgeon. S. O. 192, par. 17, A. G. O., Washington, D. C., August 18, 1890.

RETIREMENT.

MOORE, JOHN, Brigadier-General and Surgeon-General, August 16, 1890 (Act of June 30, 1882). Headquarters of the Army, A. G. O., Washington, August 18, 1890.

THE WEST INDIES AS A SANITARIUM.

BY WILLIAM F. HUTCHINSON, M.D.

CAREFUL and thorough consideration should precede decision where to send invalids for climate treatment.

Certain places are favorable for certain diseases, and these may be near together, even in the tropics; but judicious selection is not an easy matter, except the doctor is personally acquainted with the resorts he recommends, or knows some one who is to whom he can refer.

Warm climates by the sea are essentially favorable to nerve rest. Not only does the heated, hurried atmosphere lay its heavy hand upon undue mental or physical work, but examples of *dolce far niente* are seen in every surrounding picture, in every slow lounging movement of those who lend it animation. Then the voyage down to their sunny shores is often a veritable cure. Out of sight of land the voyager rests upon the heaving bosom of infinite power, and a brain that is worn out by constant study of details, or steady strain of important responsibilities, will find in the journey alone a valuable prescription.

There is total, enforced rest. Reading grows tiresome, even to well people; and such minor incidents as a passing ship or white jet of distant whale-spout, fill completely minds that are wont to be crowded with most important business. Even sea-sickness does its part in destroying memory and thoroughly stimulating the alimentary canal.

A gentleman from Albany said to me this morning at table, "I am astonished at myself. At home I never eat any breakfast, except oatmeal and cream, and here I am hungry for more after devouring three substantial steaks, and they don't disagree with me, either."

Any form of nervous prostration or mental tire is promptly benefited by these climates. It is best, I believe, to choose a residence in some island that will be permanent, where society is good and amusements not unknown, where sea-bathing may be had, and a good hotel. In this way, opportunity is afforded for one to grow accustomed to environment, and study customs of other lands, a pursuit always full of interest and profit. He will gain friends able and willing to aid him in search after lost health, and miss the confusion and excitement of shorter visits made upon a mere flying trip, and, best of all, will be afforded time for beneficial results to crystallize, so to speak, into permanent cure.

Mails are infrequent here, not arriving oftener than once in ten days or two weeks; and telegrams are such expensive luxuries at $3.00 a word that only sheer need compels their use. All sources of home worry thus cut off, and cold, stormy, northern winter only remembered with pity for such as cannot escape it, convalescence speedily begins. Rest, mental as well as physical, is again possible, and the invalid blesses sound judgment that sent him away.

Chronic albuminuria and diabetes are on the list of rare diseases here. Case after case within my personal experience has steadily gained in tropical climates, and two of my own are cured thereby, both remaining well after a year north. The perpetual skin action before spoken of, carries away urea and its compounds without troubling the kidneys. Perspiration is something astonishing to men whose skins have been dry and harsh for months, and sense of flexible, moist cuticle most agreeable. In one of my cases of diabetes in which sudorifics had been vainly tried, the first day at Nassau was marked by restoration of this function, and the sweat from any part of his body had a distinctly urinous odor, which it was more than a week in losing.

From almost constant calls to pass water, the demand ran down to four times daily, in a month; and

after the fourth night, Mr. D—— was able to sleep steadily through without a single summons.

Rapid gain of flesh followed, and although sugar did not entirely disappear during the first winter, there was a sense of returning strength and vitality, that speedily made drugs unnecessary, and that persisted all the following summer, which was spent climbing about the White Mountains. Briefly, in three winters of tropical sunshine and three summers of bracing mountain air, Mr. D. was cured. For four years now there has been nothing abnormal in his urine, and he is again effectively at the head of a great business.

So with albuminuria. In every case where kidney destruction has not progressed so far as to make even relief of symptoms impossible, I believe that a few seasons in the tropics, with judicious advice while there, will prove a cure. It must be so. Functional rest is the only form of treatment that is inaccessible north,—that nature freely furnishes in these sunny isles; and accompanying this, the valuable tonic, sea-bathing, may be taken every day in the year, in water whose tepid warmth does not over stimulate, and whose purity is guaranteed by three thousand miles of tossing before it comes to land.

There are few more delightful episodes in a sick man's existence than a change from leaden skies, howling winds, and chilling cold of northern winter to constant sunshine, soft trade winds, and delicious daily sea-baths of perpetual summer, with returning sense of capacity for enjoyment. "Life is still worth having," he says, as he gets up at five in the morning, walks down to the beach and enjoys his warm, salt-water bath. There is an exhilaration in matinal hours in the tropics that is contagious. Every thing is awake; turf, trees, and flowers are sparkling with dew; air is cool and sweet, and that vital sense which appropriates from nature its food, is completely satisfied.

It is in such diseases as Bright's that these influences are potent for good, and they are totally inaccessible in winter elsewhere.

These same powerful factors work equally well in what Americans delight in calling nervous exhaustion, when, perhaps, it is the entire system that is depleted of force.

In our party this year were half a dozen professional men, doctors of medicine and divinity, literary men and women, beside several merchants, and, with scarcely an exception, they were "all tired out." One reverend doctor, whose pleasant manners and jovial character made him a general favorite, had been ordered the trip by his physician, in the belief that his exhausted energies would be thereby somewhat restored. But he was mistaken. The clergyman, who had completely and suddenly broken down in nerve, was not to be restored in such a summary manner. He was a sufferer from sea-sickness that was enough, on a rolling ship like ours, to spoil half the voyage; and the rest was far too short for any permanent benefit. As far as it went, or could go, the climate change prescribed was well; but it is always a mistake to send a patient to sea who is a bad sailor, without a long interval of land rest before the return voyage.

This fact is not generally appreciated, I think, and many who return with but temporary or partial relief from nervous exhaustion, must bethink themselves that nothing more could be expected from such a course.

Causes that have been steadily at work for years, produce effects that are not removable in weeks, and a long, steady, complete rest, with all the environment of quiet, change of air, of scene and food, without excitement, or that hardest of work, sightseeing, is required to restore elasticity to the overstrained bow, to permit a reinforcement of nervous force in empty brain and ganglia.

Be it known at once that none of these islands offer, like European resorts, health in one hand—and a chalice of dissipation foaming full in the other. Here are only eternal summer, delicious fruit, birds that sing and flowers that bloom every day, courteous people and comfortable homes—all at trifling price.

With rare exceptions, streets are empty and people sleeping before nine o'clock. Amusements end with the day, and an hour's quiet chat at club or at home, following the usual late dinner, well prepares a nervous invalid for a calm, restful sleep. Evening parties, except in Jamaica and Trinidad, are very infrequent, and it may be said with truth that natives of the tropics devote their nights to sleep.

During the day there are beautiful drives among scenery so charming that even its novelty in the way of strange plants and flowers, is but a small factor of enjoyment, over excellent roads and at moderate prices; pleasant walks in quaint old towns, among people whose customs are frequently strange and interesting; visits to shops whose goods are unlike those in our own stores, and very cheap; strolls in early morning to market places where steady rattle of chattering negroes is as odd as are the fruits and vegetables they sell; unending experiments in new dishes at table, which are like a lottery, by no means all prizes, and, above all, the delicious sensation that when breakfast is finished, the day's work is done.

There *are* local newspapers; but in all my island life I never saw a visitor look at one. Dolce far niente indeed, within the tropics, and the hours are too few for the nothing there is to do.

So our patients with tired minds and uncertain brain functions have but to settle quietly down, say good-bye to the ships that brought them hither and regain equilibrium.

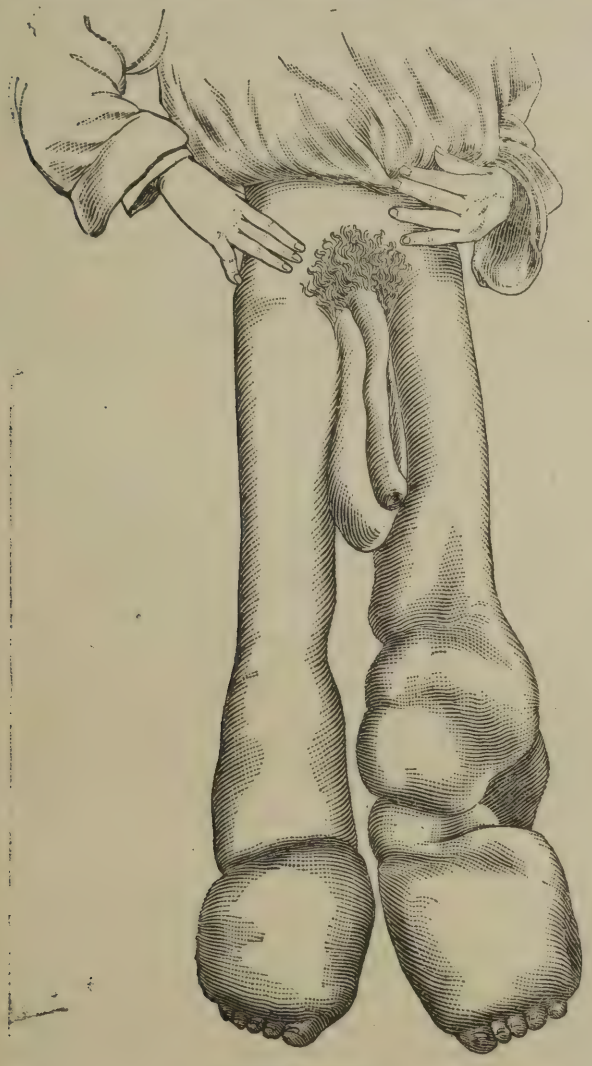
A few years ago, a secretary of the treasury gave concern to family and friends, by failing mind and feebleness of his usual vigorous judgment. Many cares of state and business had tried out his powerful physique, and with some difficulty he was persuaded to go to Nassau. Here I met him and watched his gain for a few weeks, until he felt so well that he would go back to his post. Warnings were useless, he would go. "Why, doctor," said he, "I sleep perfectly, have a splendid appetite, digest well—in fact, I am *well*. I must get back."

I told him that he was only better; that time bade fair to restore brain tone and make him strong again, but that, while certain nervous symptoms persisted as they did, he was still in danger and ought not to return to work. But remonstrances were useless, and within six months after he had resumed his portfolio, death from cerebral exhaustion claimed another shining victim.

That form of brain congestion that is accompanied with slow, full pulse and general lethargy of functions, is promptly benefited by the tropics. It is simply steady heat stimulus that does this, and accelerated skin-action. Surrounded by an atmosphere whose minimum temperature is 68°, and average 78° F., there comes speedy relief to tension of venous circulation in the head. Feet are no longer cold, hands no longer white and flabby; capillaries are full again and brain relieved, and lack of need of heavy

clothing to carry round frees from a weighty load. In a short time, pulsation doubles in force, tone and speed, and there is some comfort in living.

Neuralgias dependent upon lowered general tone, visceral disease or inflammatory conditions, are usually cured by the combined influence of sea and heat. In most islands within the tropics, these are continuous, for none of them are large enough to give inland distance sufficient for dry air, and all towns are upon the coast. A residence in one of them is like being at sea and ashore at the same time, and medical men practising there have told me that nerve pain is a rare occurrence except from wounds. It is generally the first symptom that disappears in Bright's disease brought south, and more than one case of general neuralgia from my own practice has been permanently cured by a single winter there.



ELEPHANTIASIS.

A curious circumstance in this connection is that smaller doses of hypnotics and narcotics are needed than at the North. I found that a twelfth-grain of morphia at Barbados was equal in pain killing power to a quarter-grain in New England, and five grains of sodic bromide would induce sleep in a patient accustomed to take twenty-five in Boston. Inquiry among druggists showed that their average doses of these drugs prescribed was much smaller than ours. This condition is probably caused by lack of interfering nervous excitement and greater general quiet.

Fat people grow thinner here. One lady, who weighed over two hundred when she arrived in Port of Spain, left there, after three months, happy in possession of a hundred and forty pounds and greatly increased comfort, For this pleasant result her constant profuse perspiration and a diet largely of fruit, together with daily carriage exercise, was responsible. All these scarcely attainable elsewhere, certainly not North in winter time.

Thin people, whose lankness is due to dyspepsia, find themselves eating and comfortably caring for an amount of food that would have been impossible at home, and gain weight. In seven days at Martinique I gained five pounds.

Perhaps the most brilliant results of heat in climate cure are seen in those puzzling forms of functional nervous disorder known as neurasthenia. At its worst, there are few diseases whose unfortunate possessor is regarded with more dread by his physician. There is so little to do, and the patient demands so much! Well, doctor, if you can persuade him to take the West Indian voyage, you will probably have one patient less when spring comes. Sea-sickness and fidgets are mortal enemies, and active vomiting leaves small time for querulous complaints. By the time St. Kitts is reached, the patient is ready to go ashore and enjoy novel sights as well as any one, and the entire lack of sympathy for fancied disease that strangers exhibit is a better cure than strychnine or steel. Then, whatever may have been the cause of trouble, it is gone. New surroundings, strange sights, and an atmosphere without any sharp points in it combine to keep the mind busy and soothe uneasy nerves; so that the neurastheniac finds himself wondering, some fine morning, that he has forgotten to complain.

I am assuming in this statement that there is no organic complication. When there is, I give the disease another name.

In all derangements of the heart this climate is invaluable. In valvular diseases, arterial stenosis, and fatty degeneration, great comfort follows the change. All symptoms are greatly ameliorated or disappear, and the amount of comfort obtained, almost at once, is striking. This is due, I believe, to relief of cardiac and arterial pressure by distension of skin vessels by heat and its relaxation, together with steady barometric pressure and absence of excitement. A single case in point may be cited, and might be added to by others.

A. B., an army surgeon, contracted acute rheumatism in 1861, from exposure. The attack lasted six weeks, with frequent metastasis, and was followed by endocarditis, from which an excellent recovery was made, and nothing thought further of the matter. During the battle of Antietam, eighteen months later, he was struck on the chest by a spent piece of shell, which merely prostrated him, and that also passed unnoticed. Not until 1876, fourteen years later, did serious symptoms occur, which then assumed such serious proportions that a consultation was ordered, and examination by three of the leading chest specialists in the country revealed an aortic stenosis, and they agreed that life must be brief; one of them, Prof. Loomis, giving two weeks as the probable extent.

But the doctor was plucky; and knowing, from experience, the good effect of warm climates in similar cases, started promptly for Cuba, whence he returned, after two months, in apparently sound health. All constitutional signs had disappeared, and a second examination gave greatly decreased murmur, com-

pensatory dilatation without weakness, nearly normal capacity for running and climbing, and normal muscular strength.

This state continued until winter came again, when the old weak feelings, pain over heart and down left arm, and inability to mount stairs, all returned. This time he did not wait for any consultation, but started at once for sunny lands, whence he again returned, in early spring, well.

Briefly, these journeys have been repeated every winter since, and my friend is in the enjoyment of excellent health, immense capacity for work and enjoyment, and the two weeks' lease of life has expanded to fourteen years, with fair prospects for fourteen years more, if cold be avoided.

In thus sketching briefly some diseases that are benfited by a visit to the tropics, I by no means present that climate as a panacea. Certain maladies get well there, others grow rapidly worse; and, in the next paper, it is my purpose to speak of the latter—to warn against going South, as so far I have advised it.

MARTINIQUE, W. I., March, 1890.

THE PRESENT STATUS OF HERNIA OPERATIONS.[1]

By J. W. KIME, M. D.,
FT. DODGE, IOWA.

MR. PRESIDENT AND MEMBERS OF THE IOWA STATE MEDICAL SOCIETY:

Were it not that my subject is very much simplified, by reason of the fact that I can briefly say of a large majority of hernia operations, that they have been abandoned, I could scarcely presume to enter upon the consideration of so broad a question in so brief a time. But the methods accepted by surgeons at the present day as truly meritorious are few, though the radical operation which is to cure all herniæ and annihilate the lucrative truss business, is still undevised.

Few surgeons have as yet reached that state of advancement where they must not still decide, in any given case, where to use the truss, the knife, or leave the patient to palliatives, and to the kindly processes of nature. The variety of hernia, its reducibility, the condition of its circulation, its size, contents and complications; the duration of its strangulation; the age, condition and circumstances of the patient; the efficiency of truss pressure, and many other data, still constitute the premises upon which the careful surgeon bases his conclusion.

There can be no doubt that many cases of hernia have recently been subjected to operation by various methods that should have been treated by less heroic measures; and there is danger of the radical operation falling into disrepute, except as an addendum to herniotomy made necessary by strangulation, unless greater care is exercised in the proper selection of cases for operation. The surgeon may show as much learning and skill, and frequently far more honor his profession, in withholding operative measures, as in performing brilliant feats upon patients who are either not benefited thereby, or immediately take their departure for the great beyond.

These facts may not be pleasing to the ambitious operator, but the profession insists upon their observance.

At a meeting of the New York Academy of Medicine in January of the present year, it was plainly the sense of the society, that many of the cases reported as cured by various methods, had since relapsed, so that it was at present impossible to get correct statistics of any of the recent operations, none of which have passed the experimental stage. During the discussion, DeGarmo, a leading authority on the subject, but one who strongly inclines to the mechanical treatment, stated that the reason he did so few herniotomies himself was, that it kept him busy fitting trusses to the patients the other operators had cured.

The truss, though old as the human race, is not a useless appliance of the past. It still continues preferable to operation in all cases of simple reducible hernia, where truss pressure efficiently retains the viscera within the abdominal cavity. Radical cure operations are yet too unreliable to be advised where æsthetics or convenience only recommends them; although we are aware that certain surgeons advise operation in such cases, especially if occurring in children, who may, during a lifetime, be burdened with a truss; but until they show us that operative measures are harmless, and quite certain to effect a cure, or that we are warranted in sacrificing a certain number that the remainder may be more comfortable, we will continue with the truss.

It has become an established principle of surgery that operation should be advised in all cases where the rupture can be replaced within the abdomen, but is not held there by means of the truss; though rarely, in these cases, is more accomplished than the contraction of the hernial aperture to such an extent that the truss will retain the protrusion. To this rule exceptions may be taken only in the aged, or otherwise debilitated, where much danger to life would be entailed by operation.

In irreducible hernia, especially if painful, the demand for operative measures is still more imperative; but in these cases we are often compelled, from nonconsent of the patient, to use, for a time at least, some form of appliance, as the elastic bandage, or the truss with concave pad. In this connection I will state that I have three times used the concave pad in irreducible hernia. In two cases it failed completely, in one of which I operated, while the third must soon submit to operation. The case operated was Mrs. S., aged forty four; incarcerated femoral hernia with cystic tumor of omentum; operated September 8, 1888; omentum and cyst removed; wound closed by deep and superficial sutures. A relapse of the hernia occurred six months later. Truss pressure now very efficient. Rupture has not been down for nearly one year.

In incarcerated and strangulated hernia, after reasonable attempts at reduction have been made, and in gangrenous states, we have no choice but to operate, unless the patient is already moribund when coming under our care. These latter only should be denied the advantages of operation, and left to nature's own resources. But it is truly wonderful what this intelligent agent can accomplish without our assistance. A case occurring in the practice of my colleague, Dr. Ristine, of Ft. Dodge, and to whose kindness I am indebted for the particulars, tends to make us feel that we are not always the *sine qua non* in these matters that our professional pride incites us to assume.

Fifteen years ago the doctor was refused an operation on a severely strangulated hernia. In due season an artificial anus formed, which, under pressure of a pad, gradually closed, and the man is now enjoying health at the age of seventy-five, with only a cicatrix in the groin to remind him of the doctor's certain prognosis.

[1] Read before the Iowa State Medical Society at Des Moines, Iowa, April 17, 1890.

Owing to the great frequency of oblique inquinal hernia it has been the ambition of surgeons to devise an operation that would be both safe and certain to effect a cure. Hence the many procedures recorded in text-book and journal, which not infrequently promise more than experience, at least in the hands of other operators, will warrant. Of these that have now taken their place on the historical page of hernia operations are: The use of caustics to the interior of the sac; Heaton's injections of tincture of iodine, and other irritants which excite inflammatory action; scarifications of the sac; and the subcutaneous wire method of John Wood, of London; though some may insist that these various methods should still be classed among the legitimate operations of the day.

The radical cure operations now prominently before the profession, have for their foundation principles the complete obliteration of the hernial canal, and the restoration of a smooth peritoneal surface on a level with that of the general peritoneum about the internal ring.

This is to be accomplished by either of two methods, the "open" or the "closed." Of the latter Macewen's is the one most widely and most favorably known, of the former McBurney's is the type. Macewen, after carefully dissecting out the sac, exposing it well up to the internal ring, passes a suture in such a manner that the sac is folded up into a shield or bos, and pressed firmly into the internal ring and upper portion of the canal. The wound is then closed by means of sutures, and healing takes place by first intention.

The bossing of the sac is applicable only in those cases where it is comparatively thick and in a healthy state; when injured or sphacelated, and in congenital or infantile hernia, it of course cannot be done.

This operation and its modifications have the advantage over the open method of a much more speedy recovery, and should a truss be subsequently necessary the cicatrix is much better adapted to support its pressure. When the sac, for any reason, is found unsuitable for bossing, it may be ligated at the internal ring, cut away and the canal closed with sutures as before.

Ball dissects out the sac as high as the internal ring, and twists it on itself and thus obliterates it. This plan is inapplicable in the same cases where Macewen's bossing cannot be done, and has the additional disadvantage that in the hands of an inexperienced operator, other structures than the sac may be readily included in the twist. Other operators have ligated the sac, cut and sutured in situ; ligated, pushed it into the ring, sutured it there, and closed the canal behind it; while more recently, Bryant, of New York, slits the pillars of the ring, and, after ligating the sac high up, weaves it back and forth through the slits across the canal which he treats either by the open or closed method, as may be indicated in each individual case. His report is premature, and the original plan of ligating the sac has already been abandoned, as in one case it sloughed, necessitating reopening of the wound; this, together with the fact that one other relapsed, and that he reports but three cases, does not give us a favorable impression of his plan. He now proposes to scrape the interior of the mouth of the sac and pin about one-fourth inch of it shut with a cat-gut suture, and interweave the sac. We await his results.

Weir's method of transplanting a portion of the scapula of a dog over the hernial aperture has not yet been reported upon, either as to the effect upon the patient or upon the canine, but there are many chances of its being unfavorable to both.

Of all operations now before the profession that of McBurney[1] reported February, 1889, is the one most prominent, and promises the best chance of cure of any yet devised. This has as its principal objects the securing of a smooth peritoneal surface, with ample backing in the hernial canal by means of a dense cicatrix formed from granulation tissue from the very bottom of the wound, and by the drainage it secures, reducing to a minimum the risk of septic process or purulent infiltration. After carefully dissecting out the sac, and excising the omentum, if present, he ligates the neck on a level with the peritoneum surrounding the internal ring. The sac is then cut away and the wound sutured in such a manner that it must remain open. This is accomplished by deeply inverting the skin into the wound and stitching it there. The canal is now firmly packed with antiseptic gauze, especial care being exercised to secure firm pressure at the internal ring. The entire wound heals by granulation. No truss is subsequently to be worn.

At the time his report was made McBurney had operated 31 times, with the following results: Deaths, 1; relapses, 1; unknown, 2; still under treatment, 3; cures, 24; total, 31. Of these, 21 cases were of less than 1, and all but 2 of less than 2 years' standing. So that at the time of this report the operation had not yet stood the test of time.

Of it we can only say that it promises more than any other operation so far devised; but that it is radical in the sense of cure in every case, it is not; nor in the hands of the general operator is it devoid of risk to life. The necessary handling of the peritoneum must of itself unavoidably prove fatal in some cases.

In view of the fact that should a radical cure fail to be obtained a truss cannot be so well borne as in the closed methods, the primary cures from the open method must be greatly in excess to insure final benefit to the patient.

Of five cases of non-strangulated hernia I have seen operated by McBurney's plan one, in Bellevue Hospital, proved fatal within forty-eight hours of operation. The others were still under treatment when I left the hospital.

There are few subjects, either in medicine or surgery, that demand so ready and accurate knowledge of what to do and when to do it as in strangulated hernia. There is no time for the perusal of books or refreshing our anatomical knowledge. The best methods of operating and their technique must be constantly in our possession, nor should our knowledge stop short of actual experiment with the intestinal suture; for in those cases where the gangrenous portion is high up in the intestinal tract no other means can possibly save life; but this procedure cannot be undertaken with any hope of success without that previous training, which can be obtained only from vivisection. A case recently coming under my observation painfully impressed upon me the importance of what I have stated. A lady, age 56; strong and robust, consulted me on May 28, 1888. Diagnosis of incomplete, irreducible, femoral hernia was made, and treatment advised. Patient refused to accept the diagnosis, as ten years previously a prominent surgeon of Chicago had pronounced it an inguinal gland, (and here I may remark that no mistake is more easily made, and none more fatal to

[1] Medical Record, March 23, 1889, New York.

the interests of the patient). On July 2, 1888, complete strangulation occurred and a homœopath was called, who failed to recognize the true state of affairs. He, together with his consultant from Des Moines, finally pronounced it an abdominal abscess. The abscess opened over the crural canal, and its discharge was fæces! Food and homœopathic pellets, in the shape of allopathic capsules, shortly made their appearance through the mysterious orifice.

On November 2d I was called to make a post-mortem on the case. On my arrival at the house I was informed that I would find an opening in the lower portion of the stomach, communicating with the abdominal cavity, or abscess cavity, which was a synonymous term, and that this cavity discharged at the groin.

It is needless to state that after so lucid an explanation as this a post-mortem almost seemed unnecessary. With little difficulty I found the opening in the lower portion of the stomach, but, unfortunately, it was a very normal pylorus. The intestine was also normal to a point eleven and a half feet below the stomach, where the ilium was fixed in the remains of the femoral canal.

Nature had made a noble effort, and, though ignorance opposed her in many ways, succeeded in forming an artificial anus, though too near the stomach, and death from inanition finally ensued.[1]

The surgeon would have had three opportunities to save this life: first, by herniotomy before gangrene occurred; second, by incision into the gangrenous mass, thus limiting the process of decay; and later, by intestinal suture.

The problem of hernia is an old one. Even the Divine Architect considered it, but found it impractible to pass the cord and vessels from the abdominal cavity, without leaving a weakened point of resistance in its walls, and ever since that time man has had trouble in keeping his viscera within his abdomen; and after all the investigation and surgical skill that has been applied in the solution of this problem, the pessimist might, with much color of consistency, assert that it is at least very doubtful if ever an operation will be devised that will give much better results in these cases than are now obtained.

THE PATHOLOGY AND TREATMENT OF INTRA-PELVIC INFLAMMATIONS.[2]

By M. B. WARD, M.D.,

Professor of Gynecology in the Kansas Medical College.

MR. PRESIDENT:—Inflammations of the pelvic organs and their sequelæ are the most common diseases with which the gynecologist has to deal.

In the entire scope of medical practice no subject has been so vaguely understood, and no other diseases so unscientifically treated.

It was about thirty years ago that Bernutz and Goupil, by careful clinical observations and post-mortem investigations, first described the true pathology of pelvic inflammations. Many years passed by before their researches were properly understood and appreciated. Some of our prominent teachers and authors still classify intra-pelvic inflammations as parimetritis and perimetritis, and recommend the treatment accordingly.

The demonstrations of Bernutz and Goupil in relation to diseased states of the ovaries and Fallopian tubes, together with puerperal, specific, and other infections of the pelvic organs, have now been proved true by the daily explorations of the pelvic cavity within the past few years. No two men have done more to place gynecology in the front rank of special surgery, than have Bernutz and Goupil.

I am not in the least unmindful that some in my presence may regard with no little suspicion, gynecology as a special branch of medicine and surgery. Gynecology furnishes so extensive opportunities for practical research and advancement, that there seems no good reason why it should not claim a place along with ophthalmology, otology, rhinology, and other branches already generally recognized as specialties. There is, therefore, no occasion to apologize or defend gynecology as an important specialty.

Daniel Webster once said of Massachusetts when one attempted to defame her good name, "There she stands, and the record of her discoveries and brilliant victories is ample excuse for her existence." The same is true of gynecology.

In order that you may fully appreciate the wonderful advancement of gynecology, I will read an extract from a lecture delivered by Dr. Green (not our president), Professor of Obstetrics and Diseases of Women, in the Univerity of Pennsylvania, about a century ago: The ovaria are situated about three or four fingers' breadth from the side of the uterus. They contain small pelluoid eggs, from which they take their names. We don't understand the real use of the ovaria; but as far as can be learned they are of important use in the production of the human species, as may be easily known by taking them away from any animal, which from that time forth is evidently deprived of the means of generation. We believe that both male and female contribute, and in general are absolutely necessary to the generation of the human species; and, I imagine, that the finest part of the male sperm is conveyed to the ovary, and there mixed with the liquor, and at a proper time conveyed to the uterus by the Fallopian tubes, where conception is first made, and continues to go on.

"The cure of dropsy," continues this great author, "of the ovarium by internal remedies, is the same as that of dropsy of any other parts. You may try medicines, but they will seldom succeed, as the ovarium is, in a manner, out of the laws of circulation. The only way is by paracentesis, which may be performed the same way as in the common dropsy, and it is more likely to succeed, as it is seldom like the common dropsy, attended with a scirrhous liver."

"The cure of a laceration is the same," says Dr. Green, "as that of an opening made by the falling out of the morbid spot. It is the business of nature, and all art can do is to keep the part as clean as possible."

M. Bernutz compared inflammations within the pelvis and the same process within the thorax as synonymous conditions. Skene, and some other modern writers, have utilized the same analogy to describe the pathology of intra-pelvic inflammations: "In both thoracic and pelvic inflammations, we have the croupous catarrhal process. We have pleuritis and parenchymatous inflammations on the one hand, and peritonitis and parenchymatus inflammations on the other. In pelvic inflammations we have recovery by resolution, just as in pleuro-pneumonia,

---

[1] Riedel also reports a case where inanition ensued, in which the opening into the intestine was eleven feet below the stomach, but was also eleven feet above the cæcum. While in the case here reported the distance above the cæcum was about five inches; still death from inanition ensued.

[2] Read before the Kansas State Medical Society, at Salina, May 14, 1890.

leaving adhesions and bands in one cavity as in the other. When the inflammatory process so interferes with nutrition as to destroy vitality, we have pelvic abscess in the one site, and pyothorax in the other." Bernutz further states that "uterine pathology is as certainly subordinate to a thorough acquaintance with pelvic peritonitis, as pulmonary diseases have been to a complete knowledge of pleuritis, made possible by the discovery of auscultation."

In order that I may impress with greater emphasis than it would be possible in my own language, the truth of Bernutz pathology, permit me to quote him still further. After discussing the theory of pelvic inflammations promulgated by M. Nonat, essentially that of pelvic cellulitis, which until recently held full sway in the practice of gynecologists, he says: "For some time I had no idea that the view propounded by M. Nonat was a mere hypothesis which rested on no post-mortem evidence. And it was not until after the unfortunately fatal termination of two cases, that I was able to prove incontestably that the peri-uterine tumor which, during life, presented all the symptoms of the so-called peri-uterine phlegmons, was not situated in the cellular tissue at all. In the autopsies in question, the tumor, which even after death presented all the usual signs, was seen to be formed by the pelvic viscera being matted by peritoneal adhesions. These researches then have led to the conclusion that inflammation of the pelvic peritoneum, which is the cause of the visceral adhesion, is a disease which is very commonly met with.

"Lastily, I conclude that inflammation of the pelvic serous membrane is symptomatic, and that it is generally symptomatic of inflammation of the ovaries or tubes. Thus great interest attaches to the study of this affection, and it is very important to understand thoroughly the symptoms in order to describe satisfactorily the uterine, and more especially the tubo-ovarian diseases which occasion it.

"It follows, from all this, that unless we get fatal cases to enable us to determine anatomically where the pelvic inflammation began, we cannot state positively whether it came from inflammation of the ovary or of the Fallopian tube, or whether it was caused from the puerperal state by blenorrhagia, scrofula, or any other malady. Thus we can only lay hold, as it were, of the two ends of the pathological problem—the primary diseases and the serous inflammation—the intermediate gap we can only fill up after death."

It is strange, indeed, that the researches of these great men, which constitute one of the most important discoveries in surgical pathology of modern times, should so long remain unnoticed. Their work is a lasting monument to the genius of faithful industry and a painstaking life, which all should emulate. It was, however, left for the perfected aseptic surgery of the day to fill in that "intermediate gap" in life, that they only found after "death had claimed its unfortunate victim."

Dr. L. S. McMurtry, of Danville, Ky., one of the most successful abdominal operators in the southwest, in a paper read before the American Association of Obstetricians and Gynecologists, September, 1889, stated my views so precisely, and in such choice language, regarding the pathology of pelvic inflammations, that I cannot do better than to quote his words:

"1. Intra-pelvic inflammations cannot be properly classified as parimetritis or perimetritis, inasmuch as inflammations of serous and cellular tissues cannot be separated clinically or histologically.

"2. Peri-uterine phlegmon, of Nonat, is as rare as inflammation of the cellular tissue in other parts of the body.

"3. Intra-pelvic inflammation is, as a rule, peritonitis, resulting from diseases of the ovaries and Fallopian tubes, arising in puerperal or gonorrhœal infection, or the miscellaneous infections carried to the endometrium by unclean instruments, tents or medicinal agents, or from traumatism.

"4. Pelvic peritonitis is symptomatic, never idiopathic. Pelvic peritonitis presents every grade of severity. In some instances there is a mere inflammatory spot, giving rise to but little discomfort at the time, and passing away without treatment, leaving a bare trace behind, often found post-mortem.

"A higher grade is illustrated by those instances wherein the peritoneum exhibits sub-serous congestion, transudation of serum, and exudation of plastic material. In a more severe grade there is immense transudation of serum, which accumulates in the pouch of Douglass, corresponding to pleurisy with effusion. In a very high grade the entire pelvic peritoneum is involved, the several stages of the process-congestion, and exudation are followed by suppuration, an affection of fearful proportions, and unless treated surgically, going often to a fatal issue. The sequelæ of pelvic peritonitis depend upon the vitality of the individual, the grade of the inflammatory process, and the area involved. Where the surface is limited, or may be quite extensive, recovery may take place by resolution and leave only slight adhesions behind.

"The product of inflammation may be deposited over the uterus, ovaries, and broad ligaments, leaving these organs imbedded or entangled in a mass of adhesions. As time goes on the exudate passes through repeated stages of congestion into organized tissue, with constant tendency to contraction. Pressure upon the ovaries is followed by inflammation, degeneration and atrophy of these organs. The fimbriated extremities of the Fallopian tubes are imprisoned and destroyed. At each recurring menstrual flux these bands are made tense by congestion, increased in thickness, and more thoroughly organized. In addition to lesions entailed by pressure the secretions are retained, and ovarian abscess and pyosalpinx are common results.

"When the inflammation is very intense, involving sub-serous structures, the vitality of tissues is destroyed, and one form of pelvic abscess is the result."

The diagnosis of pelvic diseases must be passed by nearly unnoticed, for the want of time to do any justice to the subject. I will ask your indulgence, however, while I briefly mention a sample of some of the cases that will present themselves to you for advice, and, probably, treatment.

The patient says she had a miscarriage, some months or years since, or, perhaps, a labor at full term, and was seriously ill for some weeks, finally got up congratulating herself that recovery was complete. "But," she says, "I do not get any strength, my appetite is, most of the time, good enough, but my food does not increase my vigor, and I do not seem to be at all as I was before." She presents a pinched expression, looks pale and anæmic, says she suffers from constipation, cannot walk or stand erect without much inconvenience, has leucorrhœa, irregular and often profuse menstruation, complains of a feeling like something is going to fall out, which she naturally attributes to prolapsus uteri. There is great tenderness upon pressure over the

ovarian region. She walks with a peculiar gait, characteristic of one with a bubonocele.

This apparent condition, with nearly all of these symptoms, may come from an attack of gonorrhœa (innocently contracted), that most insidious and damnable of all the diseases which women are heirs to; or, she may have been exposed to cold, damp weather during her normal menstruation, which resulted in congestion of the valveless veins of the pelvic organs, thus damming up the circulation; inflammation of the ovaries and tubes, and, subsequently, occlusion of the latter, are the sequelæ.

Without dwelling longer on the diagnosis, we come to inquire what treatment is to be suggested. First, what have we generally done for these cases? Have we not examined with a sound (the most dangerous of all the armamentarium known to gynecology), measuring the depth of the uterus, trying to trace its curvature, pry and twist the instrument to see how much the patient can endure without screaming, and, not unfrequently, trying to replace a supposed retroverted or retroflexed condition by a twist of the wrist, as it were, finding, most invariably, a tender and bleeding endometrium with sub-involution, patulous os, etc. And, do we not say to our patients: "Yes, madam, you have a *large, tender, bleeding, prolapsed, retroverted uterus, with ulcerated and lacerated* cervix, which will require six months or a year to cure."

Granting that the unfortunate patient has consented to try the treatment (which we judge proper), what are we in the habit of doing? Under the most careful antiseptic precautions possible with the surroundings, we dilate the cervix, curet the cervix, and, perhaps, the endometrium; apply, on a cotton holder, carbolic acid or tincture of iodine to the curetted surface, and the gaping, abraded and bleeding os; apply to the vaginal fornix tincture of iodine; replace the uterus, if we can, and introduce a cotton tampon to which is attached a silk thread, to facilitate its removal by the patient; and request the afflicted one to return two or three times a week for the same treatment; when the facts are, we are just as liable to do her harm as good, if for no other reason than this, namely, a mistaken diagnosis. The true condition being a diseased state of the uterine appendages, and the uterus is suffering from sympathy with the diseased environment.

If the foregoing is not a true picture, hold up your hand and deny it. I am certainly guilty, most guilty, but I hope none of my hearers are. Is it not true, also, that some of us have excited tubal trouble by our careless methods of conducting examinations of uterine and pelvic diseases?

Did you ever stop to consider how very difficult it is to pass a sound to the fundus uteri without carrying along with it septic germs? These germs, once lodged in the uterine cavity, are certain to migrate to the tubes, where they excite the conditions before described. Beware of the sound, that useless instrument in diagnosis—it is a relic of the past. *Do not use it!*

In this connection, permit me to digress from the main question, and say one word against gynecology, or, rather, against this feature of it. All the ills of women are not centered in the pelvis. Gynecologists ought always to try to trace the causes of disturbed functions to nerve exhaustion, intemperate or careless habits, the neglect of nature's demands, etc., rather than at once try to locate everything below the umbilicus.

There are two principal reasons for this: First, you will quite often find the cause of the diseased conditions without any signs of pelvic complications; and, second, should it subsequently be found necessary to investigate the pelvic organs to locate the exciting causes of deranged functions, you will at least have won the confidence of the naturally timid patient, and your usefulness will be thereby greatly enhanced.

When consulted by women with histories corresponding to those of pelvic diseases, our tact and skill will be put to a severe test to always know the best course to pursue. No routine plan can be always followed. I usually, however, advise my patients that their symptoms and history point to certain conditions, but would prefer to defer examination until another day, so that I can better prepare them for it. I then prescribe a saline cathartic and request them to return within the next forty-eight hours, at which time I will be able to make a more satisfactory examination.

If, upon examination, we find the patient suffering from chronic salpingitis, but in no immediate danger of serious trouble, it is well to place them on small doses of sulphate of magnesia, ten to twenty grains two or three times a day, thereby keeping the contents of the bowels softened, and with this a bitter tonic, advising the patient to feed herself well, exercise moderately, and to be exceedingly careful of exposure to wet or cold weather; and, better still, keep in bed during her menstruation, and report once each week, that she may be kept under the surveillance of her physician.

In addition to this, advise her to use a gallon of very warm water as a vaginal douche two or three times a day. Many of these cases can thus be made comfortable, at least for a time.

There will apply for advice and treatment another class of patients—namely, those who have been treated for perhaps months and years for every imaginable uterine disease, by numerous physicians of every creed, and by every method known to the profession, and out of it, and yet they are confirmed invalids!

What shall be done with this class of cases? Shall we recommend the use of electricity, and absorb the tumors, break up the adhesions, open up the occluded tubes, and spread out the congealed fimbriated extremities?

I request each of you to carefully examine these specimens of diseased ovaries and tubes which I now pass around, and then you can judge for yourselves whether electricity in any form would be likely to make of them healthy organs. Most of these specimens I saw removed by Dr. Joseph Price, of Philadelphia—some of them I have myself removed. I can, therefore, vouch for their identity in case they are so changed in form as not to be recognized.

What a blessing for all concerned it would be, if some method could be discovered to promise a cure in these cases without operative interference. None has yet been found, and the prospects are not very flattering that in our day any will be. In this connection, I cannot refrain from quoting the language of Dr. Price, the most successful and most experienced laparotomist on this continent:

"To all operators recognized as standing in the front rank of abdominal surgery, the defense of early ovariotomy is needless. In this method of dealing with abdominal diseases, ignorance and excuse for waiting are veiled by promises and explained by subterfuge, while the disease is daily making progress and its cure grows more difficult, or, perhaps, impossible.

"Who are the men who refuse to assist these patients under the conditions of which we are now speaking, or are unwilling that their patients should

have the advice or assistance of others, who hold the sufferers while they grip their fees, and, ignorantly or audaciously, tamper with human life?

"The answer resolves itself into this: Either, having stood while progress passed them, they are unable to grasp the present, or they are influenced by the base desire to hold patients who may be scared away by the suggestion of an operation; or, having given an opinion, they refuse consultation, lest adverse opinion be given and prestige be lost; or, else, they are unable to diagnosticate the condition, and hence are unable to come to a conclusion concerning it. I hold, without fear of successful contradiction, that no honest man should fear consultation. That any man is always able to come to an exact knowledge of the condition in abdominal disease, I know, is impossible, and two men, however skilful, may fail, yet, two men can come by honest conference to a conclusion approximately correct, sufficiently exact for the best interest of the patient, which will enable them at last to decide upon the advisability of operative interference."

"Who that has had any extended experience," says Dr. Bantock, of England, "of this operation, has not seen cases, far too numerous, in which the patient has been allowed to go on until the operation has become a forlorn hope? I can, unfortunately, quote too many instances of this."

Dr. Price has *never lost a case on whom he performed abdominal section for pelvic inflammations where there were no complications.*

There are a number of collateral branches connected with this subject which it was my intention to refer to, but I have already said too much, and will close by making a very brief reference to the "modern methods" of operating, stating dogmatically, and without any further explanation regarding my reasons, a few thoughts on this question:

Asepsis, pure and simple, is all that is required in any case of abdominal section. When I say simple asepsis, I do not mean that it is an easy thing to have perfect asepsis in any case, for I consider it a herculean task to make the room, fixtures, patient, dressings, water, instruments, and everybody connected with an operation, perfectly clean. It is the hardest part of successful surgery, but it is satisfactory.

Nothing, by way of irrigation, but pure warm water should ever enter into the peritoneal cavity. Drainage is always demanded when there is a septic condition present. No food of any kind should be allowed the patient for twenty-four hours after the operation. Perfect quietude must be insisted on.

Salines ought to be given freely before the operation, and promptly afterwards. No morphine at any time. The patient must be kept well protected for fear of pneumonia, and not allowed to turn on her side for forty-eight or seventy-two hours. Incision ought to be only long enough to give exit to the tumor, say on the average one inch and a-half. Instruments should be few in number and simple in construction. Silk is preferable to all sutures and ligatures. Dry dressings of the incision are best. Finally, everything depends upon the most extreme painstaking in carrying out the minutest details of the operation.

DISCUSSION.

Dr. Adams, of Kansas City, said it was a pity that time was not given to discuss such a paper. The pathology of intra-pelvic troubles was important to every physician. Never lift the uterus with a sound in replacing it. The whole field of abdominal surgery was covered by the paper.

Dr. Fabrique was pleased with the paper, but thought the incision should be longer in abdominal sections. He thinks we ought to make the incision long enough to see what we are doing. We may often want to see the trouble. The sound is a very useful instrument in diagnosis; we cannot get along without it. He thinks one can use a sound and do no damage.

Dr. Hogsett said he had a number of these cases and could not have done anything without the sound. In retroflexion and antiflexion where they are chronic, the sound must be used.

Dr. Adams said that the uterus which could be replaced by the sound does not need a sound.

Dr. Oldham said he did not hear the whole paper; but said it was important to all to know well the subject discussed in the paper, whether practising as a specialist or not. Sometimes the patient may have suffered from what is supposed to be malaria, when it is really a disease of the pelvic organs. He thinks the sound is essential in diagnosis, and not harmful when carefully used. The breaking up of adhesions is a very grave question.

Dr. Ward, in closing the discussion, said that it was very important to make the incision as short as possible in removing the diseased appendages. Nothing can be gained by a long incision, as we cannot see into the pelvis, and the shock is much greater to the patient, and there is more danger of ventral hernia. He insisted that the sound should not be used indiscriminately in the diagnosis of uterine diseases. It is not necessary to the diagnosis of versions or flexions. Explained the method of bi-manual examinations, which, if carefully practised, would enable any experienced physician to diagnose the position of the uterus without a sound.

DERMATITIS MULTIFORMIS; REPORT OF A CASE, WITH REMARKS.[1]

By W. H. DUNLAP, M.D.

A CASE of dermatitis multiformis which recently came under my observations, and which presented, in fairly typical form, the phenomena usually seen, suggested to me the idea that in addition to the report of the case, a few words in regard to the standing and classification of these particular dermatoses, which are not so rare as was formerly supposed, might form an interesting, if not especially profitable, paper, with which to appear before you. With this semi-excuse for not presenting a purely original work, I will proceed at once to a description of the lesions when first seen. The patient, a woman, presented an eruption widely scattered over the body. It was most profuse on the back—where the individual patches were so numerous as to be almost confluent—abdomen, chest, buttocks, outer and posterior surfaces of the thighs and the arms.

The forearms and legs were relatively free, though numerous scattered groups were situated in these places, special predilection being shown for the flexor surfaces. The face and hands were not attacked, though the neck and parts about the ears were well covered. Only a few lesions were present on the feet, and these were limited to the dorsal surfaces. The eruption was vesico-pustular in character, consisting of numerous pustules, a few pure vesicles and some small bullæ. Grouping was a characteristic symptom. The size of the individual lesions varied from a pin head to a split pea, and larger, but the

[1] Read before the third section of the New York State Medical Association.

greater number were intermediates. In shape they were conical within the larger ones, flattened or umbilicated apices.

The skin on which they rested was decidedly reddened and hyperæmic, the redness being especially well marked around those lesions which were frankly pustular, forming a distinct areola. In some instances, however, the efflorescences were so close together that the patches of eruption seemed to be resting on a generally intensely inflamed skin, no special areola being discernible for each individual lesion. In addition to the pustules, vesico-pustules, and blebs, there were a few papules, or hardish red elevations, scattered here and there over the body. Those parts, as the abdomen, back, thigh, etc., which had suffered most, were covered with thin, yellowish-white crusts, which looked not unlike flakes of pastry, and which were made up of the contents of ruptured vesicles, pustules and belbs mingled, with their coverings, all dried together. On removing these accumulations a smooth, shining, slightly moist, reddened surface was seen, and the same appearance was noted when the top of one of the pustules, or belbs, was removed, only, as a matter of course, greater moisture was present. There was no ulceration in either instance, merely a superficial excoriation. Where larger tracts had been freed from the crusts, as on the back or thighs, the appearance of the red and shining skin was not unlike that seen in eczema madidous. The picture presented was, as you will note, fairly varied, consisting, to sum up, of vesicles, vesico-pustules, and small belbs (which were purulent, or sero purulent as to contents), some scattered papules, and flaky crusts innumerable, together with hyperæmia and redness of the skin, varying from a lively pink to a deep and well marked red. With objective phenomena so pronounced, the patient complained but little of subjective symptoms referable to the skin itself. There were unpleasant and disagreeable sensations of burning, sensitiveness or tenderness, and some itching; not enough to call for scratching, though the patient said that *before the appearance* of the eruption most decided itching was felt, which passed away, or naturally lessened with the complete development of the rash.

The patient's general history is as follows: She is a women of the lower class, and accustomed to hard work; forty-seven years of age; twice married; mother of four children; family history negative. She has never been ill, save with the eruption. She is now passing through the climacteric. She considers her general health good, and says "were it not for the 'skin disease' she would be perfectly well." She is thin, and has a worried and anxious look. Before the first attack, four years ago, she was stout and in good flesh; but since then she has gradually emaciated. The appetite is fair; bowels irregular; sometimes loose, and sometimes constipated; complains of some intestinal indigestion. Tongue slightly furred. Temperature normal. No anomalies of cir culation. Urine negative. Temperature, however, rose in one instance to 101.5° during a relapse, and she stated that she was always feverish and chilly whenever the eruption was about to appear.

Her history of the eruption is as follows: In the spring of 1886, not long after the birth of her last child, two small "blisters" appeared on the side of her chest, just below the axilla, one on each side. These blisters dried down in the centre, and spread on the periphery by the formation of new ones, till quite a patch of disease was formed, and then healed under the use of some salve. In a short time a relapse occurred; the disease appearing on the abdomen, and spreading to the chest and back, when it ceased; and healing, another period of immunity followed till the autumn of 1886, when a violent outbreak took place, quite as extensive as the present one. From this time till I saw her, in April, 1890, she has never been entirely free from the disease, though there has been periods of comparative relief. The eruption comes in crops, before one entirely disappears, a new one develops, and thus the disease is prolonged. The lesions vary; at one time they appear as "water blisters," to quote her own words, while at others they are pustules from the start. This variation the patient thought was due to the condition of her general health; when strong, the eruption being vesicular; when run down, pustular. The outbreaks were usually, if not always, preceded by a "peculiar feeling" in the skin of the parts about to be attacked, which was followed by intense itching, lasting till the eruption was fully developed, when it passed away, and burning, tingling sensations took its place. No change in the appearance of the skin, except sometimes redness, on which later the vesicles, pustules, and blebs appeared, had been noticed; at other times the effloresences arose on an apparently perfectly normal surface, the erythema developing later. The diagnosis of dermatitis multiformis was made, and the patient put on quinine, iron, and Fowler's solution. The beginning dose of the latter was 3 ♏. t. i. d., which was gradually increased to the patient's limit of tolerance, which, in this instance, was 6 ♏. t. i. d. This quantity was continued till improvement was established. The local treatment consisted in the use of a salicylic acid (1 per cent.), starch, and vaseline paste. The diet was not restricted, except that pickles, sugars, pastries, and, generally speaking, non-easily digested foods were forbidden. In the course of six weeks the skin was nearly healed, though during this time a partial relapse occurred, affecting abdomen, thighs, and neck, which lasted about one week. In the seventh week, the body was entirely free from disease, save the flexor surfaces of the wrists, where, from time to time, during the progress of the case, a grouped, papular rash had appeared, and was still present. The site of the eruption on the trunk and extremities was marked by some redness and slight pigmentation, though no scarring, or other evidences of the disease were noticeable. The patient was ordered to continue the Fowler's solution till all of the eruption had disappeared, and then cease by gradually deminishing the dose. The iron she was advised to continue for two or three months. The quinine had been stopped in the second week of treatment. The diagnosis, as already stated, was dermatitis multiformis, and a few words in regard to this class of dermatological affections may not be inappropriate.

Since the earlier attempts at classification of skin diseases, certain anomalous forms of eruptions, characterized sometimes in their courses by the formation of vesicles, vesico-pustules, and blebs, together with other primary and secondary lesions, have been recognized as failing to come under any of the accepted varieties of skin diseases. These forms, standing in an intermediate position to, and partaking somewhat of, the clinical characters of pemphigus, the herpes group and erythema multiforme have received and been described under many names, according to the stage or variety of the disease presented to the observer. The old generic term was hydroa, and under this heading descriptions appeared, not only of cases of hydroa proper—as we understand it

to-day—but of atypical forms of pemphigus, herpes iris and bullous phases of erythema multiforme. The latitude given the term, together with a desire on the part of the profession for a more definite nomenclature, resulted in its abandonment for the most part, and, indeed, I agree with Fox that it is objectionable since, etyniologically considered, it conveys the influence of disease affecting the perspiration. Bazin, however, reintroduced the old name, and it has been accepted for this class of cases by many dermatologists in France, England, and this country, though not generally recognized by the German school.

In 1876 Hebra described a rare disease, of which, at the present time, but twelve cases have been observed, so far as I know. This disease he called impetigo herpetiformis, and it presents many of the same general characteristics, so far as the skin manifestations are concerned, of the disease under consideration. It is "a grouped, small-sized, pustular eruption, the pustules extending peripherally by the formation of new ones, thus implicating large areas. The lesions are pustular from the beginning, and start on the inner side of the thighs and groins, around the navel, breast, axillæ, or on the oral mucous membrane." The general symptoms mentioned were "rigors, high fever, loose or constipated bowels, and high colored urine." The differences between it and the hydroa forms of Bazin may be roughly stated as (1) the uniformity of the lesion, which, in impetigo herpetiformis is a small pustule and pustular from the start; (2) the limitation of the disease for the most part to the puerperal state; and (3) the generally fatal termination of the affection.

Following the work of Hebra on impetigo herpetiformis, Duhring, in 1884 and later, appeared with a series of able papers on dermatitis herpetiformis, in which he detailed a number of cases which, in their clinical aspect, corresponded very closely to those already described by other writers under the names of hydroa herpetiformis, pemphigus pruriginosus, herpes gestationis, herpes circinatus, bullorus, etc. He even went so far as to attempt to include under this head the impetigo herpetiformis of Hebra; but, admitting the correctness of Duhring's generalization for most cases, this view is not universally accepted, since impetigo herpetiformis is held to have characters of its own sufficiently distinct and positive to justify its classification as a separate disease. The papers of Duhring, with one by the late T. Fox, on a "Clinical Study of Hydroa," together with numerous monographs and reports of cases from many other sources, have done much to clear up the former chaos of views, and give us a fairly clear and definite idea of these clinically varied eruptions. The result of these labors has been the unification of the phenomena and their classification under one of the following heads (the terms being regarded as synonyms): hydroa, dermatitis herpetiformis or dermatitis multiformis. Impetigo herpetiformis being generally regarded as a disease *sui generis*, I have chosen the name dermatitis multiformis as more perfectly covering the ground, since one of the principal factors in diagnosis is the polymorphism in the clinical appearances of the disease.

Having thus briefly referred to the history and noted the present unification under one of these heads of the varied manifestations of the disease, let me for a moment call your attention to the principal symptoms, as described by different observers, and, comparing those of the case reported with them, see how far they agree.

(1) Dermatitis herpetiformis, or hydroa, is described as a "chronic, multiform skin affection, occurring in successive outbreaks, the eruption being at one time herpetiform or vesicular, at another pustular; or, again at different periods in the same case, erythematous or wheal-like lesions or bullæ may predominate."

The case reported is essentially chronic: there have been successive attacks, broken by periods of freedom. The first eruption was vesicular; at present it is pustular. Erythema, papules, vesicles, pustules, and blebs have all been present at the same time, thus showing its multiformity.

(2). In dermatitis herpetiformis, the lesions are usually grouped or arranged in circular form, and grow peripherally by the formation of new efflorescences on the borders. In one case the lesions were distinctly grouped, though this characteristic was only noticeable in the newly-developed patches, the crowding together of the individual efflorescences and the great extent of surface involved marking this symptom in the fully developed and older eruptions. Peripheral extension was a specially noteworthy trait of the early attacks.

(3) In dermatitis herpetiformis, itching and burning sensations are usually very severe. The same is true in this case, the itching being specially well-marked *preceding* the appearance of the eruption and *during its early stages.*

(4) So far as location is concerned, the agreement still continues, with the natural differences which the special case always exhibits when compared with the type variety. In both instances the eruption was bilateral; in both were abdomen and flexor surfaces of thighs, arms, and legs affected, while the parts below the knee were comparatively free. The back, it is true, was violently attacked in the case reported, which is not usual, but the variation goes no further.

(5) The course of dermatitis herpetiformis is essentially chronic; relapses are frequent, occurring at intervals of weeks or months, or even longer. Here, again, coincidence is noted, for already this case has lasted four years and several relapses have taken place during this time, and while the patient has at present returned to her home comparatively well, I do not anticipate that the improvement will be permanent, but look forward to a recurrence some time in the future, though it may be months or even a year or so distant.

(6) Finally, the report shows that, during the progress of the case, all the varied phases of eruption peculiar to this class of skin diseases have, at some time or other been present. At its commencement, occurring shortly after childbirth, it might quite properly have been called a herpes gestationis; when the lesions consisted of vesicles in groups, the term dermatitis herpetiformis would have been most fitting. But, considered as a whole, the broader name chosen seems more suitable.

Having thus shown that we are dealing with a fairly typical case of dermatitis multiformis, permit me a word or two, in closing, as to the pathology and treatment of these affections, which more widely extended knowledge and closer observations have shown to be more frequent than was formerly supposed.

As to the pathology, little can be said. Most writers agree that the nervous system is somehow concerned, since cases occur in the overworked, the fagged, the depressed and excited. One author says: "Its occurrence during pregnancy, and recurrence in subsequent pregnancies, show that there is some causative relationship, probably reflex irritation of

the vaso-motor center, and the irritation of this center, either direct or indirect, is the most probable pathology."

Bazin favors a gouty predisposition as a cause; while other observers fail to note it in their cases. Probably future investigation will corroborate the vaso-motor theory, thus allying the disease quite intimately to the pemphigus and erythema multiforma groups.

So far as prognosis is concerned, this seems as unsettled as the pathology. For the milder and purely vesicular forms it is generally good; while for the pustular and severer varieties it is unfavorable. In all cases the probability of relapses should be mentioned, and no cures "guaranteed."

The treatment is comparatively simple. After attending to the ordinary rules of hygiene, change of air, good and easily digested food, etc., our choice of remedies is limited to quinine, arsenic, and belladonna. T. Fox preferred quinine, which must be given in large doses, and which often succeeds admirably. Of the three drugs, however, arsenic is more uniformly successful. It must be given in large doses and pushed to the patient's limit of tolerance, when usually new efflorescences cease to appear, and healing begins. This is generally affected in four to six weeks. Should quinine or arsenic, one or both, fail, then belladonna may be tried. I have never had occasion, in my own practice, to use it; but others say that, in doses of fifteen to thirty minims of the tincture, thrice daily, it has done good service.

Locally, only the simplest applications are needed. Mild and soothing ointments containing boracic or salicylic acid, the ordinary zinc ointment, etc., are amply sufficient. When burning sensations are marked, cooling lotions sometimes act better than ointments. Should the itching be very violent, washes containing carbolic acid, the liq. carbonis detergens, or other antiseptics may be applied.

THE DELSTANCHE INSTRUMENT FOR MASSAGE IN CERTAIN AFFECTIONS OF THE MIDDLE EAR.

By W. CHEATHAM, M.D.,
Lecturer on Diseases of the Eye, Ear, Throat, and Nose, University of Louisville.

THE treatment referred to in the title of this article is quite old, and has many times dropped out of use, and as many times revived. Woakes and others have invented or originated many instruments to carry this treatment out, only to be laid away and forgotten. Theoretically the principle is good, but practically the results have not been so encouraging. While away this summer I met, in Brussels, Prof. Delstanche, an aurist, to whom Prof. Rossa, of New York, had given me a card. I found many of Prof. Delstanche's methods quite interesting and curious. On his operating table he keeps a small kettle holding some antiseptic fluid, and in it no less than thirty silver custachean catheters, the fluid in the kettle kept boiling by means of a gas-jet under.

Prof. Delstanche, when examining an ear, holds his mirror in his mouth, instead of having a forehead band or spectacle frame. I have here with me to-night an instrument originated by Prof. Delstanche to massage the middle ear, to break up anchylosis and adhesions, and to give free motion to an otherwise motionless drum and ossicles. He has two styles of the instrument, the smaller one being intended for hospital use. I think it the best instrument of the two, and by attaching a Seigel's oloscope to it the amount of motion in the membrani tympani can be studied, and the plunge set accordingly. The newer and larger instrument can also be attached to this glass tube and used to cup, or as an artificial leech; but it is as an instrument to massage the middle ear to which I wish to call attention to-night. Some old cases of catarrh of the middle ear with anchylosis of the ossicles, and adhesions of the membrani tympani to the inner wall of the drum cavity, with tinnitus and vertigo, cases on which I had tried all other treatment, and in which I had used the Seigel's oloscope attached to a large ear syringe, and had used the same oloscope by suction with the mouth, with no benefit. It is in such cases as these in which I have used the Delstanche instrument with some benefit. How long this benefit will last I do not know. Men who have used similar instruments say the benefit is of but a few weeks' or a few months' duration. It occurs to me that if the benefit is even so short as that it is of much service, as in a majority of such cases nothing is of service; and such a condition of things makes many people wish for death, and drives some to suicide.

Mrs. R., a widow, thirty six years of age, has what Rossa calls proliferous inflammation of both middle ears. Deafness, tinnitus, and vertigo are hardly bearable; there is little or no tube trouble; considerable inflammation on lateral walls of pharynx. This woman I have treated for years; her trouble has gradually and steadily increased, notwithstanding. She is deaf to all conversation in the left ear; can scarcely hear the loudest voice in the right ear. I continued the inflation as before, and, some weeks ago, commenced using the Delstanche instrument—as yet with no effect in the left ear, but with a most agreeable result in the right. After three weeks' treatment she hears one speaking in a common tone of voice with the mouth close to the right ear. She says she always feels better after its use. I have never used it on one yet who did not ask for it the next treatment. When I first commenced using the instrument I caused some pain, and have occasionally produced small hemorrhages of the M. T., or into the walls of the canal. This apparent violence, which in some cases leads to a little after-reaction, has had much to throw such instruments into disuse. I have used this Delstanche instrument many times, and have yet to have any permanent disagreeable results follow. As I stated before, the patients always ask for it again.

Another use to which I put it is to cleanse out small pockets in obit. med. suppurativa, and to draw pus from the middle ear when the hole in the M. T. is either small or high up.

This little instrument can be put to many uses with much profit. I believe if properly and carefully used, it will relieve many of those cases (as much as they can be relieved) in which removal of the M. T. and ossicles is now advised. None of the cases in which this operation has been done have gotten permanent relief, yet the operation is advised and performed; some of them doing well for a year or more, then gradually going back to their old condition.

The larger instrument of the two, I forgot to say, can, by closing or opening a little vent, be converted into an instrument for suction alone, or suction and compression.

THE *California Homœopath* reports a new natural mineral water, called "Skookem Limechen Chuck," "a remedy for all ailments." Next.

TREATMENT OF GONORRHŒAL BUBOS WITH PARENCHYMATOUS INJECTIONS OF IODINE.

By P. S. DONNELLAN,

Licentiate Royal College of Surgeons and Physicians, Ireland; Member of the Medico-Chirurgical College, Philadelphia.

MR. X., aged thirty-five years, consulted me on the second of June, and stated that a week previous to his visit he noticed a swelling in each groin, which grew larger and more painful on exertion. On examination I found he had a well-marked gonorrhœa, the existence of which was unknown to him, but he admitted it must have been the result of contact two weeks before. I also found a large bubo in each inguinal region, each measuring two and one-half by one and one-half inches. The possibilities of abscess formation and subsequent disfigurement being explained to him, he agreed to carry out any treatment that would prevent such a complication. This being the case, I adopted a plan of treatment which has been very successful in similar cases amongst the soldiers of the British army—viz., absolute rest in the recumbent position, with the continuous pressure over each bubo, of a shot-bag containing eight ounces of fine shot. He was placed on a light diet of milk, soups, etc., alcohol in any form being forbidden, and given the following mixture:

℞.—Antimonii et potassæ tart. ..... grs. iv.
Magnesiæ sulphatis ..... ℥ j.
Elixir simplicis. ..... ʒ iv.
Aquæ cinnamomi q. s. ad..... ʒ ij.
M. et Sig.—A teaspoonful in water night and morning.

As the patient was of plethoric habit, this combination acted well as an antiphlogistic and saline cathartic. For the gonorrhœa the following injection was prescribed:

℞.—Morphinæ sulphatis..... grs. ij.
Ext. hydrastis fluid..... ʒ ij.
Bismuthi subnitratis ..... ʒ j.
Mucilagis acaciæ..... ʒ iv.
Aquæ destillat q. s. ad..... f ʒ iv.
M. et Sig.—Half an ounce to be used as an injection night and morning; the patient being instructed to wash out the urethra with a two per cent. solution of boracic acid, before using the injection.

Under this treatment he improved rapidly; the gonorrhœal discharge ceased on the fourth day, and the bubos diminished to the size of filberts. Unfortunately, however, before the cure was complete, he had to resume his occupation, which was a very active one, and, at the end of a few days, he returned with the bubos as large as before, though there was no return of the gonorrhœa. As his business engagements rendered it out of the question to resume the old treatment, he was directed to rest as much as possible, and each night to apply tincture of iodine to the enlarged glands. I also gave him gradually increasing doses of potassium iodide, commencing with gr. iii, well diluted, after each meal, with the object of promoting absorption. After a week's trial, as the results were not very encouraging, I decided to try the parenchymatous injection of tincture of iodine, so successfully employed in the treatment of hypertrophied tonsils, goitre, etc., and injected ten minims of tincture of iodine (U. S. P.) into the substance of each tumor every alternate day. The improvement was most gratifying; after the third injection the bubos had almost disappeared, and at the end of a fortnight, it would have been difficult for the most careful observer to have detected any enlargement of the affected glands.

It seems to me that in these cases of gonorrhœal bubo, where the patient, owing to business engagements, is unwilling to remain at absolute rest—where suppuration is almost inevitable and its prevention of the highest importance—the parenchymatous injection of iodine is specially indicated.

A few points are to be observed in administering the injections. The hypodermic syringe and needle must be sterilized by being boiled and afterwards washed with a solution of hydrarg. bichlor, 1 to 5,000. The site of the proposed injection must also be made aseptic in the usual way, and sprayed with a four per cent. solution of cocaine to render the operation painless. Ten minims of the tincture of iodine are now drawn into the syringe, the needle elevated, and the piston slowly pushed in to expel any contained air. The needle is carefully washed with the bichloride solution, and about three minims of a four per cent. solution of boracic acid is drawn into the syringe, the object of this being to prevent any of the iodine coming in contact with the subcutaneous tissue, and thus avoiding the danger of setting up a suppurative inflammation. For the same reason the needle must be passed vertically into the substance of the tumor, before its contents are discharged. These precautions being observed, the operation is entirely without danger, and in my hands I have found it quite successful.

Society Notes.

PENNSYLVANIA AND MARYLAND MEDICAL ASSOCIATION.

THE thirteenth annual reunion of the Pennsylvania and Maryland Medical Association was held August 28, at Highland Park, York, Pa. The meeting was in every particular a success. It was opened by an address of welcome by Dr. T. C. Gable, of York, President of the York County Medical Society. After welcoming the guests on behalf of the society, Dr. Gable briefly outlined the history of the association, and dwelt upon its social nature, saying that they had not assembled for the discussion of scientific problems, but for the enjoyment of the hour and a kindly interchange of social feelings.

The address of Dr. Gable was fittingly responded to by Dr. J. M. Deaver, President of the association. Short addresses were also delivered by Dr. J. F. Packard, of Philadelphia; Dr. John Morris, of Baltimore; and the Mayor of York.

The addresses were followed by the annual dinner, after which the business portion of the meeting was transacted. The following officers were elected:

President, Dr. J. J. Jamar, Elkton, Md. *Vice Presidents*, Dr. J. F. Packard, Philadelphia; Dr. J. Montgomery, Chambersburg, Pa. *Secretary and Treasurer*, Dr. T. S. Livingstone, Columbia, Pa. *Executive Committee*, Dr. A. Craig, Columbia, Pa.; Dr. J. A. C. O'Neil, Gettysburg, Pa.; Dr. S. J. Rouse, York, Pa.; Dr. W. T. Bishop, Harrisburg, Pa.; Dr. W. W. Dale, Carlisle, Pa.; Dr. H. C. Whiteford, Darlington, Md.; Dr. J. Morris, Baltimore, Md.; Dr. Ewing, Chester, Pa.

The business being disposed of, dancing was indulged in until dusk. The attendance was good, about two hundred physicians, including their families, being present. The place of meeting was well chosen, the day all that could be desired, and the entertainment the most enjoyable. Altogether, the executive committee deserve great credit for their management, and the members of the association may indeed be congratulated upon the complete success of their thirteenth reunion. THE TIMES AND REGISTER was the only medical journal represented. Among the Philadelphia physicians present were Drs. Packard, Deaver, Edward Jackson and Eastlake.

PHYSIOLOGICAL THERAPEUTICS.

IN the *Dietetic Gazette*, Mrs. Rorer quotes the remark of an old physician, to the effect that he would have no trouble treating diarrhœa or dysentery, if he could put his patients in splints. One of the unsolvable problems in medicine is how to induce people to take a due amount of rest, exercise, etc.; in fact, to regulate their habits in accordance with their physiological requirements. It would be a judicious thing to change the title of the physiological chair and denominate its incumbent Professor of the Art of Prolonging Life. This would assist the student in forming some conception of the fundamental importance of this branch. As it is, principally from our own fault in not duly enlightening our patients, the latter take their doses religiously, and generally forget all about the hygienic regulations. It is so much easier to take a teaspoonful t. i. d. than to eat less meat and take more exercise, etc.

An instance of this neglect of physiology came before us lately. A young and successful business man complained of some sluggishness of intellect, indisposition to work as hard as usual, but rather to let things take their own course; continually recurring attacks of catarrhal laryngitis with suffocative sensations; night-sweats, and a decided diminution of sexual activity. He had been unusually active in his habits, but of late had given up his athletic sports and at present takes no exercise worthy of the name. At the same time he was leading a happy and regular life, without monetary anxiety, and he had retained the good appetite and digestion of his active period; even adding to his dietary the use of a moderate quantity of wine. To the resulting plethora all the symptoms are due. Colchicum, salicylic acid and salines give prompt relief to these, and help to confirm the evil; as the knowledge that a few glasses of Friedrichshalle will fix him all right is taken by the patient as a license to indulge in the pleasures of the table. The proper prescription is the regulation of his physiology. He must have animal food once daily; plenty of fruit; no hot drinks or wine; but Seltzer or Underwood water as his only beverage. The Underwood water is almost as pure as distilled water, having only two grains per gallon of solid matter, in which there is neither iron nor organic matter. It is the only native rival of Apollinaris. One must learn to appreciate the great hematogenic powers of the chalybeate waters, to comprehend the absolute necessity of excluding them from the treatment of plethora. For present relief, a walking trip of a week's duration, to be followed by an hour every day in the racket court or at lawn tennis, completes the prescription.

It is not without reason that physicians are said to lose their faith in drugs as they grow older. As they learn the properties of these agents by continued experience, so they learn their limitations; and too often the exhibition of medicines is but a weak excuse for the violation of physiological law. And yet, when we realize that by following the directions here given, this man's death will be postponed many years (and is not death the greatest of human ills, which one hundred thousand doctors in the United States devote their lives to fighting?) the enormous comparative value of the physiological treatment is apparent. But this involves a degree of self denial of which many men are incapable; and they are apt to think that the living a physiological life involves, to quote Rudyard Kipling, "harder work than the importance of this world justifies."

For this reason it is important to apply the remedy at the proper time and in appropriate doses.

First of all, enlist the wife on your side. We will not dilate upon this direction, the importance of which is obvious.

Secondly, send your patient off on the week's walking trip, and to insure congenial company and close adherence to orders with the avoidance of overexertion, and, for many other reasons, go with him yourself.

Finally, when he comes home radiant with health, his head cleared of the nitrogenous fogs, his appetite and slumber recalling the golden days of youth, attack him suddenly with the question, "Would you not like to always feel as you do now?" Then is the time to lay down the law to him, to direct his feet into the straight and narrow path of physiological morality.

The laws of God and man have placed in our hands one of the most powerful of our means for combatting disease: the Christian Sabbath. The utilization of this day in accordance with the divinely-appointed laws of physiology can be made more actively beneficial to our patients than all the calomel in all the pharmacies.

CAPITAL PUNISHMENT.

THE fanatic who recommended mutilation of criminals in order to exterminate the species and permit only a Spartan-like survival of the fittest, was perhaps, after all, on a higher round of the ladder of civilization than his cotemporaries who adhere to the law of capital punishment. The Judaical law of the shedding of blood for blood long ago, gave place to the alternative, "He that is without sin, let him first cast a stone," restricting the right to take life to the Power that endows life; and yet, this same

law of blood is held as a precedent by the barbarians of our day, who judicially murder the criminal. The substitution of electricity for the gallows may be a degree advanced in mercy, but a complete revision of the existing statutes will alone erase the stain that marks every form of capital punishment.

The ancients treated their sacrificial victims like princes, and led them to the altar loaded with garlands of flowers. A fickle and sentimental public of our day feasts the condemned man with danties, and strews his path to the gallows with flowers. The death sentence, that offspring of the law of vengeance, thus transforms the murderer into a hero and a martyr.

We punish the murderer by annihilation, ridding the earth of his foul presence. We try to train the vicious beast, we kill the vicious man. Is this practice consistent with our supposed intelligence and refinement? Punishment inflicted only for retaliation is brutal; when imposed, also, with the view of reforming the culprit, it is just and humane, and the ends of the law are as well served.

The law is designed not only to punish the offender, but to prevent the commission of crime. Does the dread of death-sentence stay the hand of the assassin when his heart is swayed by hot-blooded impulses or steeled by premeditated villainy? At the moment the blow is struck there is no reasoning power to discriminate as to the quality and degree of punishment.

It is urged that the penalty of imprisonment for life cannot be satisfactorily enforced while political corruption has the power to unlock prison doors and release unworthy criminals. Granted that a guilty man would thus occasionally be liberated, may there not, at present, be many an innocent man sent to his death, on circumstantial evidence, by the verdict of men selected for their superior inability to form an opinion? The drop has fallen beneath the feet of many a convict who has protested his innocence to the last moment of his life.

The prohibition of the pardoning power in capital crimes, except on actual proof of innocence, might make imprisonment for life an effectual possibility. The criminal thus removed from contact with the outer world would have no opportunity to further offend the law; while, by a judicious system of convict-labor, he could be made self-supporting.

There is wisdom and dignity in a law which, instead of cutting off a guilty wretch red-handed in crime, sullen and remorseless, gives him the chance, while under punishment, to fully realize the enormity of his offense, and its consequences, so that softened and purified by repentance and wise discipline, he may work his progress to a higher mental and moral state of existence. When by natural laws his career is ended, he is better fitted to pass into the life beyond, not murdered, but reformed, as well as punished, through the justice administered by an enlightened community.—A. M. G.

[A curious instance of two minds pursuing the same line of thought is shown by comparing this editorial with an article in the *St. Louis Globe-Democrat*, of August 17, by Dr. Maurice. Not only are the same ideas expressed, but even the quotations are identical. It is, perhaps, well to add that Dr. Maurice's paper did not come to hand until after the present editorial had been completed. Those who feel an interest in the subject will find Dr. Maurice's paper exceedingly interesting. Ed. TIMES AND REGISTER.]

Annotations.

THE COUNTRY DOCTOR.

THE country doctor is often overslaughed by the supposed superiority of his city confrére; but occasionally the rural member has an opportunity to get back in good shape. At the recent meeting of the Ohio State Medical Society, Dr. R. H. Reed, of Mansfield, reported a case of hematoma of the ovary, upon which he had operated successfully, the result fully verifying his diagnosis and vindicating his skill as an operator.

We are informed by the *Columbus Medical Journal* that previous to the operation the patient had been sent to a well-known city surgeon for diagnosis and advice. This person examined the case, promised a written opinion which he never gave, pocketed his fee, and said all he could to destroy the patient's confidence in her doctor—telling her his diagnosis was mistaken and operation unnecessary; adding some very unjust remarks upon the folly of patients trusting their lives to incompetent country surgeons, instead of coming to the city where men like himself were to be found. The matter is aggravated by the fact that this city surgeon is a Professor of Surgery in a medical college, and on hundreds of diplomas his name is to be found, certifying to the qualifications of these country doctors whom he traduces.

If the facts of this case are as stated, Dr. Reed ought to carry it before the State Society. If such outrageous disregard of ethics be permitted to go on unpunished, our noble profession would degenerate into a greedy, snarling mob. But it is rarely safe to put such credence in the stories of patients as will justify the publication of the offender's name. People exaggerate, often unconsciously; and things sound very differently after transmission by word of mouth. So that, unless one has the most direct evidence of the wrong-doing, it is better to say nothing, and simply avoid having consultations with the man in future. And if we can persuade ourselves that our informant has misunderstood the tenor of the remarks, it is infinitely better for ourselves than to believe a fellow physician capable of such treachery.

Letters to the Editor.

POISONING BY DRIED BEEF.

I HAVE an interesting instance of poisoning which I wish to report. Its interest attaches as much to the origin of the poison as to the cases themselves. The poison in this instance came from eating the ordinary dried beef of the market. I have never seen a case reported from such a source, nor do I find it mentioned in any of my works on toxicology.

The history of the case is as follows: On the night of July 7, 1890, I was called to visit the family of Mr. M. When I arrived I found three members of the family in bed. They had eaten supper at 6 P. M. as well as usual. I found Mr. M. lying on the bed with his face buried in his pillow. George, the one son,

was vomiting profusely, and this was attended with a great amount of retching and violent purging. Miss L., who was boarding at the house, was quiet, but complained of excruciating pain in the region of the stomach and a great amount of nausea, but up to this time she had neither vomited nor purged. They had eaten supper together at 6 P. M., and all took sick within a few minutes of each other. The family consisted of Mr. M. and wife, three children, two boarders, and the housemaid. From inquiry I learned that George (fifteen years old) had experienced a severe burning sensation in the stomach, which was soon followed by vomiting. The mother going across the street for Mr. M. found him in the same condition, and a few minutes later Miss L. appeared, showing like symptoms. All three took sick about 9 P. M., or three hours after eating. On examination I found the temperatures of all subnormal, pulse from sixty to sixty-five per minute, great prostration and nervousness; the vomiting and purging were continuous, and accompanied by extreme pain in the hypogastric region, dryness of the mouth and throat, and in the son there was considerable difficulty experienced in breathing. I was told the supper had consisted of bread, butter, cake, sliced tomatoes, and dried beef. At this time none of the other members of the family were affected, though they all ate of the dried beef, which we concluded produced the trouble. They had eaten nothing else at dinner except canned corn, but Mr. M. had not touched this. I diagnosed the cases as acute arsenical poisoning, and prescribed the peroxide of iron well diluted with water, intending it to act both as an antedote and by their vomiting to wash out the stomach.

I asked for consultation when Dr. Abbott was called. After examining the patients he concluded that it was either the result of arsenic or ptomanies.

At 11 P. M. we administered the one-eighth of a grain of morphine and a half-drachm of bismuth subnit. to Mr. M. and to George, and now Miss L. had her turn at vomiting. I gave her freely of the peroxide of iron and water until I felt sure her stomach was completely emptied. After having given Mr. M. and George the morphine and one or two doses of the bismuth they experienced decided relief, both from the nausea and the crampy pains.

While their pulse had been diminished both in force and frequency they did not demand immediate stimulation. Miss L., on the other hand, was profoundly affected. The pulse became imperceptible at the wrist, and for half an hour she remained in a semi-unconscious condition, but after giving her brandy hypodermically she rallied, and at 1 A. M. her pulse was sixty-four per minute, and quite strong. I left them then for the night. Mrs. M., not feeling well, concluded to take a dose of Epsom salts before going to bed, though she supposed her trouble due to the excitement and worry of the evening.

The next morning, Mrs. M. thought she felt as well as usual, nothing further than a little weak from the effects of the physic. But now the housemaid was in bed. She began purging about 4 A. M., and when I arrived, at 8 A. M., she was suffering considerably from nausea and the depressing effects of the poison.

The temperatures were all normal, except that of Mr. M., which still remained subnormal. The pulse, however, was slow, in all ranging from sixty per minute (in Mr. M.) to sixty-four. There was considerable pain over the stomach on pressure, and the crampy pains were still quite severe at intervals.

On visiting them again, in the evening, Mrs. M. complained of a severe pain under the right arm, which extended up through the scapular region. At times it was quite severe. Her temperature was subnormal ($97\frac{4}{5}°$); pulse, sixty-four beats per minute, and considerable nausea. I ordered her to bed, and prescribed one-eighth grain doses of morphine, and one-half drachm doses of bismuth, every three hours, together with brandy at frequent intervals.

The next day I visited them, and found them about the same, nothing further than that Mr. M.'s temperature had risen to normal, and the housemaid, who was having her regular monthly period, was slightly feverish (99.5°).

On the fourth day, Miss L.'s and Georgie's pulse came up to normal, seventy-two and seventy-six per minute, but Mr. and Mrs. M.'s pulse continued at sixty-five. I saw them again on July 15. They were then all up and around, but were still complaining of want of strength, backache and occasional spells of nausea.

As I have indicated, my treatment consisted of the peroxide of iron as an antidote, and, finally, when I was satisfied that the stomach was completely evacuated, I administered morphine sulph. one-eighth grain every three hours, and bismuth subnit. in one-half drachm doses every half-hour until they had taken four doses, then every fourth hour; brandy being given during the depressant stage.

Carelessly, I forgot to obtain a piece of the meat the first night, and the next day when I asked for it, I was unable to do so, it having been thrown into the "waste basket;" and the butcher, fearing that it would injure his business, refused to give me a piece. So I was unable to have it analyzed.

I last saw these patients August 18, and none of them had entirely recovered from the effects of the poison. They complained of loss of appetite, some pain in the hypogastrium, with frequent spells of diarrhœa, and incapacity for work.

Now, the question with me is, what was the poison in these cases? Was it arsenic? Then, where did it come from? Or, was it ptomanies?

Can we determine which of the two poisons is causing the trouble without an analysis of the meat; if so, what are the points in the differential diagnosis?

C. L. McCann, M.D.

Fluid cosmoline..... fʒij.
M.—S. Half a drachm to be injected through a soft rubber catheter passed in to the tender spot in the urethra.

—*Waugh.*

BACELLI recommends the intravenous use of quinine in malarial cases of the severer types. His formula is as follows:

℞.—Quinine hydrochlorate..... 15 grains.
Sodium chloride..... 1⅛ grains.
Distilled water..... 2½ drachms.
Filter, warm, and inject into a vein of the forearm, under strict antisepsis, during the sweating stage.

FOR ASTIGMATIC HEADACHE.—Gelsemidine sulphate $\frac{1}{200}$ gr. every half hour will give great relief.

—*Jones.*

WOMEN DOCTORS.—Women who practise medicine suffer from inconveniences at times, as for instance. A man rang a door bell of a female physician at night, crying: "Quick! Tell the doctor to hurry, as my wife is about to be confined." Then the husband of the female physician, who had opened the door, responded: "It is impossible for the doctor to go at this moment. She is about to be confined herself."

—*Lancet Clinic.*

CHATTANOOGA AS A HEALTH RESORT.—I will close with this brief summary: Chattanooga as a health resort presents herself as a place with a pleasant historic interest.

A city easily accessible from all parts of the Union, with a varied and extensive change of scenery; with climatic conditions, all told, unsurpassed by any point in this country.

In comparison with her neighboring cities, her death-rate is the smallest, and her sanitary and sanatory conditions greatly increasing.

And, finally, the variety of diseases is limited, they can be well treated, and with the most gratifying success in the vast majority of cases.

—Townes, in *Jour. Amer. Med. Asso.*

NEW REMEDY FOR PEDICULI PUBIS.—The treatment of pediculi pubis by the usual blue ointment has so many inconveniences with its disagreeable application and its toxic after-effects, that the use of the well-known antiparasitic action of salicylic acid has of late been much extolled. The formula is:

℞.—Salicylic acid..... 2 to 3 parts.
Aromatic vinegar..... 25 parts.
Alcohol (eighty per cent.)..... 72 parts.

The parts are to be rubbed with a piece of flannel wet with the mixture. One application is usually sufficient. Sulpho-calcine is also excellent in this trouble, as well as innocent of any irritation in its application.—*Kansas Med. Journal.*

METHACETINE.—Methacetine occurs in shining, white, odorless and almost tasteless scales. It is an active antipyretic, three, four, or even five degrees being lost within a few hours after the administration of a therapeutic dose. In doses of two or three grains given to a child it exerts a marked antithermic action, the reduction of temperature being gradually produced, and remaining at the lowest point several hours, then gradually increasing. Frequently marked perspiration is produced within an hour after its administration. It has been employed in pulmonary tuberculosis, tubercular meningitis, and in pneumonia, the patients all being children. In one case it produced slight collapse, but never vomiting, ringing in the ears, vertigo, or erythema. In its action methacetine is said to correspond in every respect to phenacetine.—*North Carolina Med. Journal.*

FROM the following extract from the *Medical Press and Circular* we infer that our distinguished fellow-citizens who attended the Birmingham meeting were not received with that cordiality they had a right to expect.

"From what we can gather, the large batch of American doctors who 'took' Birmingham in on their road to Berlin, feel very dissatisfied and hurt at the

way in which they were received, or, rather, not received. To show their discontent, most, or at any rate many, of them left Birmingham early in the week, shaking the dust from their feet on an association which has treated them so scantily. We shall probably hear more of it when the malcontents, many of whom are medical editors, have had time to pen their complaints to their respective journals. It will be interesting to know whether it was an unduly stern janitor or some less humble official or officials who has thus aroused their susceptibilities."

RUFFER reaches the following conclusions in regard to the processes taking place in the diphtheritic membrane:

1. The bacilli of diphtheria are present in the most superficial part of the membrane only; that is, in a place where they are well within reach of medicinal agents—an observation not without interest from the point of view of treatment.

2. In the diphtheritic membrane there is an active struggle taking place between the amœboid cells in the membrane and the micro-organisms. In other words, the diphtheritic membrane is a battle-field for amœboid cells and the pathogenic microbes of diphtheria.

3. The reason why the bacilli do not actually penetrate into the tissues is probably that, as soon as they try to do so, they are arrested by the amœboid cells present in the diphtheritic membrane.

—*Brit. Med. Jour.*

THE TREATMENT OF DYSPEPSIA BY CANNABIS INDICA.—At the Académie de Médecine M. Germain Sée read a paper on the Treatment of Dyspepsia and Certain Other Gastric Affections by Cannabis Indica. He said that the drug should be employed in the extract, at the dose of one-third of a grain three times a day. It acts by suppressing the painful sensations experienced after the ingestion of food, and excites the appetite. However, when an excess of hydrochloric acid is present in the stomach, large doses of bicarbonate of soda should be given at the end of the digestion in the stomach, that is to say, four hours after food had been taken. The Indian hemp had no effect on atony or dilatation of the stomach, but it acts favorably on spasm and vomiting of a nervo-motor origin. In the case of pyrosis the effects of the drug were very pronounced. In conclusion, M. Sée said that cannabis indica was an *effectual sedative* of the stomach.—*Medical Press and Circular.*

ERRATIC PAIN IN LABOR.—At the meeting of the Virginia Academy of Medicine and Surgery, held July 8, 1890, at Richmond, Va., Dr. Johnston reported the following case:

Dr. Johnston had been called, fifteen or twenty days before expected delivery, to a woman, the mother of four children (good labor each time), who complained of a severe pain, paroxysmal in character, occurring on the right side of the neck, and extending down upon her chest to the margin of the axilla. Suspecting the approach of labor, he asked for an examination, but was refused. Early the next morning he was called again, and found the child born. The pains had increased in length and intensity, the intervals growing shorter, until there was suddenly a gush of waters, the birth of the child immediately following. The woman had not a single uterine or abdominal pain, and did not, in the least, suspect the real condition of affairs.

—*Virginia Med. Monthly.*

TREATMENT OF PURULENT PLEURISY.—At a recent meeting of the Société des Hôpiteaux, Dr. Bucquoy communicated some observations of the highest interest on the treatment of purulent pleurisy. They clearly show that "lavage" of the pleura after thoracotomy, and less so after several and repeated lavages, have not the importance which is accorded to them. He summarized his remarks by the following precepts: To operate early, without which there will be produced thick fibrous shells, which cicatrize with difficulty. To practice the operation according to the rules of antisepsy, and to apply antiseptic dressings; to introduce a large drain, permitting the easy escape of the discharges, and frequently to wash the drain to prevent its being blocked up. The cure is often very rapid, the pus becomes serous, and diminished in quantity. Eventually the tube drops out and cannot be put back into its place, and in three days after the wound is cicatrized.

—*Journal of the American Med. Association.*

THE idea of taking away a piece of the vertex of the cranium in order to relieve the pressure exercised upon the cerebrum by prematurely ossified sutures, is certainly a bold conception. M. Lannelongue, however, has recently performed the operation in two cases of micro-cephalus with idiocy, and the results have, surgically, been perfectly satisfactory. The operation consisted in making an incision through the vertex of the cranium, a finger's breadth from the sagittal suture, and extending between the frontal to the occipital sutures, but not involving the dura mater. The scalp wound healed by first intention, and the relief of the tension was promptly followed by a marked increase in the intelligence of the little patients, while the signs of idiocy were modified. It remains, of course, to be seen how far the brain will thereby be enabled to make up for past deficiencies, but the operation itself, though a bold one, is based on carefully-reasoned anatomical and pathological considerations which fully justified the attempt.—*Hosp. Gazette.*

NERVE RESTORATION.—Dr. Glück reported a case before the Medical Society of Berlin lately of a man who was stabbed on the outside of the forearm with a table knife, in August, 1887. The wound was treated in the usual way, but in September complete paralysis of the parts supplied by the radial nerve was found to have taken place. An attempt was then made to reunite the ends of the divided nerve. After careful search for the peripheral and centripetal ends it was found that they were two and one-half inches apart, and that they could not be brought together by any possible means. The ends were then freshened and loosened from their surroundings, and indirectly united by means of catgut loops. Healing took place in ten days. Electrical treatment was then carried out under the direction of Prof. Bernhardt. In the course of a year complete restoration of function had taken place, which the speaker observed could only have been effected by actual growth of nerve elements along the tract of the catgut threads.

COCAINE IN THE PTYALISM OF PREGNANCY.—A young and very fleshy woman who was pregnant for the first time suffered extremely and became rapidly emaciated. She had the worst form of ptyalism with incessant running from the mouth, obliging her to have a spittoon by her bed or couch all the time. She also had a very distressing nausea, but with little

vomiting. She was highly scrofulous, and had formerly had some eruption about the anus, under the arms, on the eyelids, and on the neck, for which she had received treatment from a physician previous to her marriage. Beside the usual treatment I tried the effect of local cauterization of the uterine cervix with carbolic acid, which old expedient has benefited some of my cases very decidedly, but it did nothing for her. I then gave three hypodermics of five drops each of the five per cent. solution of cocaine at intervals of three days, keeping her quietly in bed meanwhile. The relief was direct and complete, and, although still very weak, she got up and went about without any further trouble. She was safely delivered of a nice boy on the 16th day of July.

—Carlson, in *The Clinique.*

Lanphear, of Kansas City, in an article (*Medical Review*) favoring the cathartic treatment of peritonitis, says:

1. The saline treatment should be adopted early in simple, acute peritonitis.

2. Small doses of calomel may be given to mild purgation in cases seen after the disease is fully developed.

3. Cases which fail to be relieved by cathartic measures should receive early operative interference.

4. Whenever peritonits has gone on to that stage where the formation of pus is known, or even suspected, to have taken place, abdominal section and drainage are imperatively indicated.

5. When the existence of tubercular peritonitis is diagnosticated, or strongly suspected, operation (exploratory incision) is justifiable.

6. Opium is only indicated in the second stage of peritonitis, and then not because it "forms a splint," but because it relieves pain, sustains the heart and prevents shock—thus combatting the tendency to death.

How Homœopathy Strikes the Briton.—Mr. Brudenell Carter's violent letter, in a recent number of the *Lancet*, in reference to the action of the Ophthalmological Society on a motion of his reflecting on the relations between a certain surgeon and a homœopathic practitioner, has not met with the support he, perhaps, expected. On the contrary he is roundly "slated" by four different correspondents—among them that doughty champion of homœopathy, Dr. Dudgeon. We cannot go into the merits of the case, and will content ourselves with echoing the words of our contemporary, that "the day is probably not far remote when persecution, ostracism, or censure for difference of opinion in belief, will be regarded as not only immoral but absurd. We believe that the best—and, indeed, the only—plan of getting rid of the objectionable features of the legendary homœopathist, would be to absorb and assimilate the sect. Professional digestion ought to be equal to even such a tough morsel, for many mightier unorthodoxies have been swallowed without apparent discomfort in centuries gone by.—*Hosp. Gazette.*

Food for Convalescents.—Cooking for the convalescent is sometimes more difficult than for the very sick. I have always had the feeling that the cook, nurse and market-woman should be one and the same person. A good nurse must certainly be a good cook, and a good cook must certainly be a good market-woman, and whether she goes to the market or not must know how to choose the best things for their purpose, and should have the faculty of skilfully turning all materials to good account. For instance, if she is obliged to use the white of an egg for a milk shake, the yolk should be saved for another dish, if not for the sick room, for the family use. When beef tea is made, the refuse meat may be made into a soup for the family dinner, and while much of the nourishment is gone, the soup additions will make it all that is necessary. The delicacy of cooking frequently depends also upon the cleanliness of the cooking utensils. In feeding the sick this point should be carefully looked into, as the flavor of an unclean saucepan will frequently destroy the patient's appetite for several days. Porcelain or granite iron vessels are best, but those with tin linings will answer, providing the linings are really tin, not lead, and are scrupulously clean.—*Dietetic Gazette.*

Extraction of Dislocated Lenses From the Eyes.—At the meeting of the American Ophthalmological Society, held July 16, 1890, Dr. C. S. Bull, of New York, read a paper on the extraction of dislocated lenses from the eye, whether transparent or cataracious, in which he maintained that in the majority of cases it was possible to extract a lens, dislocated into the vitreous, by external manipulation, without the introduction of any instrument into the eye. The manipulation may be described as follows: The lids are held open by a wire speculum, and the section made upwards with a narrow knife. The speculum is then removed, and the upper lid lifted away from the ball with a wire elevator. Pressure is then made against the lower part of the eye-ball, the pressure being made directly backward; the lens will be seen to rise and to appear at the pupil. Sometimes it comes through the pupil, but occasionally the use of a blunt hook or wire spoon becomes necessary. If continued pressure fails to push the lens through the pupil, or occasions prolapse of the vitreous, some other method must be substituted. For a number of years he had not found it necessary to introduce a spoon into the vitreous chamber to remove a dislocated lens floating in the vitreous.

—*American Journal of Ophthalmotology.*

Cold Baths in Typhoid Fever.—M. Debove, in a paper read at the last session of the Paris Société Médicale des Hôpitaux on the treatment of typhoid fever by cold baths, declared that he had not been convinced by a recent paper of M. Merklen that this was the best treatment. His own mortality during the last six years was 11 per cent., or during the last two years 9.2 per cent. Now, M. Merklen estimates the mortality from typhoid in Paris hospitals treated by cold baths as 9.92 per cent. M. Debove does not prescribe active medication, but believes in keeping up copious diuresis. To this end he supplies his typhoid patients with abundance of liquid, and if the quantity of urine passed does not appear to him sufficient, he "stimulates the zeal" of the attendants to get the patient to drink more; the total amount of fluid which should be taken daily ought, he says, to be not less than five or six quarts. M. Debove, who does not deny the good effects of baths, suggests that they are probably due to the increased quantity of urine secreted, which, as in the case where diuresis is produced by drinking, carries off the *materies morbi* from the system. According to M. Gérin-Rose, who followed M. Debove, still more successful results may be obtained by carrying out the following indications: (1) To produce intestinal antisepsis by means of naphthol and salicylate of bismuth, (2) to lower the fever by means of very large doses of quinine and

warm baths (at 86° F.), and (3) to keep up the patient's strength. Of forty-three patients treated during the last eighteen months in this way only one died.—*Lancet.*

Hepatic Abscess.—At a recent meeting of the Academy of Medicine of Paris M. Hache related the history of four cases of abscess of the liver, of which two were cured and two died, and made the following observations: Pain in the hepatic region, fixed, limited, and exasperated by pressure, whether irradiating to the shoulder or not, may be considered as one of the best symptoms of the existence of an abscess. The pain may be very violent without being accompanied by any complication in the peritoneum or the pleura. However, too much importance cannot be given to it as an indication of the exact locality of the purulent seat, as the abscess may be at a certain distance.

Widening of the intercostal spaces is a consequence met with in all enlargements of the liver, but where one or two are abnormally enlarged the surgeon would be right in supposing that under that spot the liver was more particularly enlarged. Fluctuation cannot be obtained unless the abscess is superficial. Exploration of the organ, even with a large trocar, is inoffensive, but M. Hache preferred the needle, as it allowed to seek for the abscess if not found at the point supposed. As to the subsequent operation, the advantages of incising simultaneously the liver and the abdominal wall, as recommended by Little, were in his mind very doubtful. The after-treatment is simple. All washings or injections should be proscribed if the abscess flows freely and without odor. Iodoform powder poured into the drainage tubes is sufficient. The prognosis must be based on the general condition of the patient, and especially of the digestive tract, for anorexia and diarrhœa are the two great enemies to be dreaded.

—*Medical Press and Circular.*

Farinaceous Foods in the Rearing of Infants.—A hospital physician sends us the following notes of his experience with five children:

A, was suckled only a fortnight, afterward had many different kinds of food, but none agreed until Robb's nursery biscuits were given, on which she began to thrive immediately. Previously her bowels were loose and the motions unhealthy; the first motion after the biscuits were commenced was natural.

B, was brought up on Hard's farinaceous food, beef-tea, and sago, and milk diluted with water. She throve fairly well.

C, was brought up on Robb's biscuits, alternated with milk and water, until he could take beef-tea and sago. He used to vomit the least crumb of bread that was given him.

D, was brought up on Robb's biscuits mixed with water only, which agreed well. Milk and water (once tried) purged him though the milk was good. At three and a half months he still took the same biscuit-pap without milk, except twice a day, when a little milk was added. This was to replace the breast which he had for over three months, but only twice a day.

E, pined away, and got very thin with Robb's biscuits, but throve upon milk and sago; the napkins were quite green till he got the sago. He was nursed not quite a month. He got into quite good condition with milk and sago.

All these children reached adult age and passed through most of the ordinary children's maladies without severe symptoms. D, when aged three, had laryngismus badly for some time, but grew a fine, vigorous youth, although there were some traces of struma. C, had late rickets at a public school, probably from insufficient superintendence of the dinners.

My impression is that farinaceous foods do not quite deserve all the hard things that are said of them, and that while they may be sadly abused if given alone, cases are not rare where they may be of much use. Another point to be emphasized is the marvelous diversities of temper of young children's viscera, the manifold idiosyncrasies so frequently met with.—*Medical Press.*

The Proteids in the Urine in Various Forms of Albuminuria.—The conclusions reached by Paton are as follows:

1. Senator was right in his conclusion that, in all cases of albuminuria, both of the chief proteids of the blood plasma are present.

2. The proportions of serum albumin and serum-globulin may vary within wide limits, the quotient of the amount of serum-albumin, divided by the amount of serum-globulin, being sometimes as low as 0.6, sometimes as high even as 39.

3. In acute nephritis, when blood is absent the quotient is high; when hæmaglolin is present, the globulin is, of course, in excess.

4. As the disease becomes more chronic, the quotient sinks, and in the terminal stages of the disease may sink as low as 0.6. This alteration depends upon the condition of the patient rather than upon the state of the kidney, and is probably related to a similar change in the blood plasma.

5. Amyloid disease cannot be distinguished from the ordinary forms of chronic nephritis by the high proportion of serum globulin, as was formerly maintained by Senator.

6. Maguire's suggestion, that functional albuminuria is characterized by the high proportion of serum-globulin, is not correct.

7. In every case the proportion of the proteids to one another varies much in the course of the day, and, in comparing the proportion of these proteids in different cases, it is necessary to examine specimens of the mixed urine of the twenty-four hours, and to take into account the nature of the diet.

8. The proportion of serum-globulin is always highest during the night. It falls greatly after breakfast, when it reaches its lowest point in the twenty-four hours. In most cases it again rises in the evening. The precise connection of the alteration in this proportion with the taking of food cannot be considered as definitely settled.

9. Milk diet, as observed by Lecorché and Telamon, has a peculiar effect in increasing the proportion of serum-albumin.

10. The amount of proteids passed appears to bear a tolerably direct proportion to the amount of proteids taken, and, excluding milk diet, the increase of the proteids in the urine on a diet rich in these substances appears to be chiefly due to an increase in the serum-albumin.

11. The variations in the proportion of the albumin to the globulin in the urine is frequently so great that we can hardly believe that it is connected with a similar change in the plasma. The few experiments we have performed would suggest that a high pressure favors the transudation of serum-albumin, while a low pressure increases the proportion of globulin transuded.—*Brit. Med. Jour.*

ACUTE CONVULSIVE SEIZURE, THE RESULT OF FISH-BONE IN THE RECTUM.—June, 1857. The author was suddenly summoned to Murray street, Ottawa, to Mr. J. S., aged fifty-seven years, a man of strong habit of body and usually most vigorous in the discharge of business, being a grocer. While behind his counter he was seized with a severe convulsive fit, which had passed over in the space of half an hour. On recovering consciousness his first expression was: "Oh, what a tearing in my bowels!" It being Lent period of the year, and fish the chief source of diet, it occurred to me that a bone might be lodged in the folds of the rectum. The bowel was at once explored. Without much effort I detected a considerable-sized fish-bone imbedded in the rectal folds, and, this being removed, he experienced almost immediate relief. This case at once opens up some interesting points as to nervous distribution in and about this part of the alimentary canal. The cerebro-spinal and sympathetic systems have an important part to play in nervous rectal force. The sacral plexus, as well as the mesenteric and hypogastric plexuses, are the chief collateral centers of reflex and influence. It is now a settled point that contraction of the external sphincter muscle is in part, at least, due to the influence of *a nerve center located* in the *lumbar region* of the spinal cord. This very nerve center is subject to various influences, and the varied distribution of the spinal nerves serves to explain the reflex symptoms of such a case in the present. Through the alimentary tract, how frequently are convulsions the result of imperfectly assimilated food, thus demonstrating how such disturbing influences stir up remote nervous centers, telegraphing, as it were, a convulsive message to the unfortunate sufferer. The ano-vesical center of man has recently been considerably cleared up by the careful observations and deductions eliminated out of cases of injury, as well as lesions of the terminal extremity of the spinal cord and its nerve roots. Kirchoff is of the opinion that the *vesical center* is situated in the conus medullaris, in the region of exit of the third and fourth sacral nerves. One of the most important functions of the spinal cord in its action as a reflex center, normal or abnormal, as the case may be, and in the discharge of the duties of professional life we are constantly reminded of the vast and varied manifestations which spring from spinal and ganglionic nervous centers, quite irrespective of the complex nervous mechanism of brain tissus *per se*.

—Sir James Grant, in *Canada Lancet*.

OUR esteemed contemporary, *The Country Doctor*, corrects our statement that we alone had the hardihood to speak a good word for Billings' census questions, as the *Doctor* himself not only advocated them but filled up and forwarded his blanks. He adds, apropos of our remark concerning the next investigation plum to be given out, that *he* had no mercenary motive in his advocacy.

We are glad of it. Such virtue should be rewarded; and to show our appreciation we will cheerfully dispose of all chance we have of receiving any favor from John S. Billings to the *Doctor* for the sum of two cents, payable in postage stamps not used more than once. Those who are so proficient in ancient history as to remember the Ninth International Medical Congress and the course of the Philadelphia *Medical Times* in that matter, will appreciate our generosity.

TABLE I.—*Anatomical Changes in the Varieties of Hepatic Cirrhosis.*

Varieties.	Size.	Color.	Surface.	Capsule.	Consistence.	Bile Passages.	Position of New Growth.	Newly-formed Biliary Canaliculi
Alcoholic	Usually small	Pale olive.	Granular.	Thick.	Tough.	Nearly empty.	Round groups of acini.	Present.
Cardiac or cyanotic	Usually large.	Dark.	Smooth.	"	"	" "	In centers of acini.	Absent.
Biliary	" "	Olive or pale.	"	Slightly thick.	"	Dilated and full of bile.	Around single acini	Abundant.
Diffuse syphilitic	Large	Brown.	"	Opaque.	"	Normal or empty.	Diffused.	A few only.
Gummatous	Irregular	Pale.	Irregular.	Thick and opaque in places.	Cartilaginous in places.	Normal.	Irregular.	Absent.
Tubercular	Large.	Pale or normal.	Smooth.	Normal.	Normal.	"	Around single acini.	Very abundant.
Malarial	"	Dark pigmented.	"	"	Tough.	"	Around single acini.	Absent.
Scarlatinal	Normal.	Normal.	"	"	Normal.	"	Around single acini.	"
Rachitic	Large.	Pale.	"	"	Tough.	"	Around single acini.	Present.
Diabetic	"	Dark and pigmented or pale.	Granular or smooth.	Thick.	"	"	Generally in centers of acini.	Absent.

TABLE II.—*Clinical Features of the Varieties of Hepatic Cirrhosis.*

Varieties.	Age.	Sex.	History.	Ascites.	Jaundice.	Hæmatemesis.	Size of Liver.
Alcoholic	Adult.	Usually male.	Abuse of alcohol.	Present in two-thirds.	Absent until later stages. A subicteric tinge then only.	May occur.	Usually small
Cardiac or cyanotic	Any age.	Either.	Chronic heart disease.	Not uncommon.	Occasional late.	Absent.	Enlarged.
Biliary	" "	"	Early jaundice.	Absent.	Present and persistent.	"	"
Diffuse syphilitic	Childhood.	"	Hereditary syphilis.	"	Absent.	"	"
Gummatous	Adult.	"	Acquired syphilis	May occur.	Occasional.	"	Irregular.
Tubercular	Any age.	"	Tubercular disease elsewhere.	Absent.	Absent.	"	Enlarged.
Malarial	" "	"	Prolonged malarial infection.	"	Frequently present.	"	"
Scarlatinal	Usually in childhood.	"	Scarlatina.	"	Absent.	"	Normal.
Rachitic	Childhood.	"	Rickets and chronic gastro-intestinal catarrh.	"	"	"	Enlarged.
Diabetic	Adult.	Usually male.	Diabetes.	"	Absent, but skin may be bronzed.	"	Generally enlarged.

Medical News and Miscellany.

No news is bad news—to editors.

EDINBURGH doctors treat one half her population gratuitously.

THE medical college in Nashville has opened an infirmary for private patients.

LONDON is now supplied with tea compressed into cakes, like the Russian bricks.

PROFESSOR WILLIAM F. WAUGH has returned from his annual tour of the Western cities.

CORONER'S PHYSICIAN H. B. TAYLOR, M.D., has been ill from an attack of blood poisoning.

SEVERAL cases of scurvy have been found among the prisoners confined on Blackwell's Island.

A CHICAGO chemist claims to be able to produce aluminum at a cost of fifteen cents per pound.

PATENT medicines have paid the British Government over $1,100,000 in duties during the present year.

UNDER the present statute in Missouri, a person can marry, be divorced, and be married again in thirty-one days.

NEAPOLITAN doctors warn against the native oysters; as they are obtained from water contaminated with typhoid sewerage.

DR. RICHARD A. CLEEMAN, of Philadelphia, was severely injured, last week, by falling on the rocks at Natural Bridge, Virginia.

A TRAINED nurse in Bellevue Hospital gave a patient a drachm of pure carbolic acid by mistake. Death ensued in an hour.

CAMDEN was cut off from its water supply last week owing to a leak in one of the supply pipes at the Pavonia pumping station.

DR. CHARLES P. GRAYSON has returned to the city after an extended visit to Narragansett Pier and other New England resorts.

THE analytical chemist and expert, Dr. Henry Leffman, addressed the Farmers' clubs of Solebury, Horsham and Wrightstown last week.

HARLEM endures an epidemic of fleas. Insect powder proves powerless against the pest; but sulphur fumigation is said to be more effectual.

"NOW that cotton is coming in," writes a Georgia editor, "we will be able to pay ten cents on the dollar in liquidation of our last year's debts."

DR. TREUFEL, of Stuttgart, and his bride (Blanche Willis Howard), will make a visit during the coming season to the father and friends of the latter at Bangor, Me.

DR. SAMUEL G. DIXON, the well-known bacteriologist, has resigned from the University of Pennsylvania, to accept a position at the Academy of Natural Sciences.

QUITE a sensation was created in Newark, N. J., last week, by the finding of the dead body of a young woman who was supposed to have been dissected by a medical student.

A REVOLUTION is taking place in the drinking habits of the Japanese. The rice brandy, which has so long been their national beverage, is rapidly being supplanted by beer brewed after the German method.

IF anything would convert a reasonable man to homœopathy, it is the report of the N. Y. S. P. A. Committee on Adulterations. Of specimens of acetic acid which should have been identical, one was seventeen times the strength of the other.

THE late International Congress was attended by 8,831 persons; made up as follows: Germans, 5,561; ladies, 1,379; non-medical, 116; Americans, 623; English, 353; French, 171; Italians, 140; Russians, 471; Turks, 12; Portuguese, 5.

CHOLERA still spreads, and there are rumors of its appearance in several of the great European centers of population. These generally prove to be cases of cholera morbus; viewed through the medium of fear or the desire of cheap newspaper notoriety.

DR. JUSTIN has succeeded in bursting another gun at Perryville, N. Y., with the usual accompaniment of scores of miraculous escapes among the three hundred spectators. The time and place for the next accident have not been named.

IT is stated that a Bohemian has discovered a combination of chemicals, by the use of which the hardest stones can be dissolved and molded into any shape, the "cast being as hard as flint, translucent, and capable of taking on a brilliant luster."

THE ninth annual meeting of the Surgeons of the Wabash Railway will be held in Decatur, Ill., on the second Thursday of November, 1890. This is the First Surgical Association of Railway Surgeons ever organized, and the meetings have always been of great interest.

COL. WEBER has adopted an effectual method of securing attentive subordinates. A consumptive Hungarian having been allowed to pass through the e nigrant office by Dr. Emiteras and Clerk Conradson, Col. Weber has decided to return the immigrant to his home at the expense of the negligent officials.

DR. H. M. FISHER, Secretary of the American Forestry Association, of which Governor Beaver is President, announced that the Association will hold its annual congress at Quebec, beginning September 3. A telegram received by Dr. Fisher from Quebec yesterday says that Prince George with a number of ships of war will be there.

MORE or less successful attempts have been made to graft nearly all the different tissues of the body, including skin, bone, teeth, muscle, nerves, glands, eyes, mucous membrane, etc. Dr. W. G. Thompson now reports a successful experiment in brain-grafting, a small piece of the brain of a cat being made to grow on the brain of a dog.

GODFREY recommends periodate as a general disinfectant application, especially to cancers; also a spray in whooping-cough, and in the early stages of tubercular consumption. Great improvement followed its use in all of nine cases of phthisis, in which it was used. It is not toxic to human beings, but is a more powerful germicide than sublimate. Internally it may be given in pill, 2 to 4 grains thrice daily; and to children in solution made by boiling 1 grain in an ounce of water.—*Med. Press.*

It is not easy to tell just when the hay fever season begins or when it ends. There are those unfortunates who find themselves smitten by the disease with the earliest spring, and who begin to sneeze with the coming of the first lone swallow, even despite the assurance of the proverb that no summer can come of his making.

There was a great similarity in the manner of death of the late John Boyle O'Reilly and his compatriot, the late Charles G Halpine, better known as "Miles O'Reilly." The latter died in 1868 from an overdose of chloroform taken to alleviate pain and induce sleep. Mr. O'Reilly died from an overdose of chloral taken with a like intent.

The New Jersey State Board of Medical Examiners is constituted as follows: *Regular*—W. P. Watson, of Hudson Co.; G. W. Brown, of Monmouth; W. L. Newell, of Salem; H. S. Wagner, of Somerset; and H. C. Hendry, of Essex. *Homœopathists*—A. Uebalacker, of Morris; and A. H. Worthington, of Mercer. *Eclectic*—E. Tiesler, of Essex.

Judge Thayer, of Philadelphia, says that no person can be legally compelled to leave his home and be treated in a hospital, even if he have small-pox or other contagious disease; it is the right of the patient to stay in his home, if he so desires. It is reported that, through ignorance, physicians sometimes aid in compelling patients to leave their homes.

The Alvarenga Prize of the College of Physicians, of Philadelphia, consisting of one year's income of the bequest of the late Dr. Alvarenga, of Lisbon, has been awarded to Dr. R. W. Philip, of the Victoria Dispensary for Consumption and Diseases of the Chest, Edinburgh, for his essay on pulmonary tuberculosis, which will be published by the college.

The *Medical Record* says that seventeen fatal cases of poisoning from antipyrin occurred in one week in Vienna, during the prevalence of the influenza. In many of these cases the drug was bought by the victims themselves, without a physician's prescription; but, partly in consequence of these fatalities, it is now illegal to sell antipyrin except upon a written prescription from a physician.

Dr. Wetherill, of the State Board of Lunacy, late of the Pennsylvania Hospital for Insane, was in Franklin last week, and investigated into the treatment of an imbecile boy by his father, John Young, of Canal. The condition of the boy was very bad, and Dr. Wetherill has applied for a writ to have him removed to an asylum; his father, although fully able, does not wish to bear the expense.

Of taste, an exchange says that it is not equally distributed over the whole surface of the tongue. "There are three distinct regions or tracts, each of which has to perform its own special office or function. The tip of the tongue is concerned mainly with pungent and acid tastes; the middle portion is sensitive chiefly to sweets or bitters, while the back or lower portion confines itself entirely to the flavors of rich, fatty substances. This subdivision of faculties in the tongue makes each piece of food undergo three separate examinations, which must be successively passed before it is admitted into full participation in the human economy."

In his recent address at the Berlin Medical Congress, Dr. Robert Koch, the eminent bacteriologist, aroused much interest by the announcement that the near future might witness the development of a method for the prevention and cure of pulmonary consumption. As reported by the *Medical Record*, Dr. Koch said that "he had not only succeeded in conferring upon guinea pigs, which are known to be peculiarly susceptible to tuberculosis, perfect immunity against the disease, but had also discovered means of averting the growth and multiplication of tubercle bacilli after inoculation."

The Mississippi Valley Medical Association will hold its sixteenth annual session at the Liederkranz hall, Louisville, Ky., October 8, 9, and 10, 1890. Prominent men in medicine in the Mississippi Valley have been prompt in sending in their names to go on the program. Outside of the Valley the Association is to be honored by the presence and papers of Drs. John A. Wyeth, of New York, and Frank Woodbury, of Philadelphia. The local arrangements are on a grand scale. Louisville knows how to entertain the stranger within her gates. The Association devotes itself entirely to the pursuit of knowledge during the sessions, having no time for quarrels and little spite works. The evenings are devoted to pleasure. The President of the Association is Dr. Joseph Matthews, of Louisville; Secretary, Dr. E. S. McKee, of Cincinnati; Chairman Committee of Arrangements, Dr. I. N. Bloom, Louisville. The American Rhinological Association will meet at the same place and the same time.

The first number of the journal of the State Medical Sodiety, of Arkansas, is before us, in the shape of a neat pamphlet of forty eight pages. The contents consist of the transactions of the society and two original papers, with the editor's salutatory.

In this direction we welcome the appearance of new journals, and hope to see the day when the medical profession will read and support its own journals, and not depend on book publishers and manufacturers for its periodical literature.

The July number of the *Columbus Medical Journal* comes to us in a greatly improved form, with new type, enlarged pages, and less than two months behind time. We are pleased to note the evidences of progress in our contemporaries.

During the month of July the deaths reported in New York City and State were as follows:

	City.	State.
Cerebro-spinal fever	16	54
Typhoid fever	31	96
Malaria	12	55
Scarlatina	24	45
Measles	63	91
Erysipelas	7	12
Whooping-cough	61	129
Croup and diphtheria	125	290
Diarrhœa	1,208	2,864
Acute lung disease	300	706
Phthisis	428	1017
Puerperal diseases	28	60
Other digestive diseases	392	1,024
Urinary diseases	217	497
Circulatory diseases	162	543
Nervous diseases	296	1,092
Cancer	78	242
Accident	187	553
Old age	46	395
Unclassified	573	1318
Total	4,254	11,083
Under five years	2,509	5,602

A NEW private hospital has been started in Halifax under the auspices of the Church of England. Two professional nurses have come out from England to take charge. Instead of the usual staff, patients may be attended by any physician they may choose, and all denominations are admitted.

—*Maritime Med. News.*

THE American Association of Obstetricians and Gynecologists will hold its next annual meeting in the City of Philadelphia, on Tuesday, Wednesday and Thursday, September 16, 17, and 18, 1890, in the hall of the College of Physicians, corner Thirteenth and Locust streets. All physicians interested are invited to attend the several sessions. Dr. E. E. Montgomery is President; Dr. Wm. Warren Potter, Secretary.

THE fourth of the first series of Health Talks, under the direction of the National Woman's Health Association was given August 28, at 1229 Chestnut street, by Dr. A. Victoria Scott, continuing the subject of "First Aid to the Injured," and referring specially to hydrophobia.

The second of the second series was the same afternoon, at 4 o'clock, before the Woman's Club of St. Paul's Church, by Dr. Caroline M. Dodson. The topic was "Every-day Accidents and How to Meet Them." These talks are free to all.

CHARLES H. HEIST, proprietor of the Monument House, Doylestown, met with a singular accident last week. Going to the ice-chest for a piece of ice, the draft of warm air entering the chest when he raised the lid exploded a porter bottle. The pieces of broken glass were thrown in every direction. One piece struck him on the left wrist, cutting a deep gash and severing the main artery. Another piece struck him on the bridge of the nose, cutting to the bone. The blood spurted in a stream from the wrist wound. By pressing hard on the artery above the wound, he checked the flow of blood until the arrival of Dr. F. Swartzlander, who was hastily summoned and dressed the wound.

JUST as Henry George is more discussed here than at home, so Bellamy's "Looking Backward" finds its greatest army of serious students in crowded, discontented England. His notion of a public umbrella has been put into operation in a new street just opened at Brixton, where the sidewalk is sheltered by a glass roof ten feet wide, supported by slim, graceful pillars rising from the curb. Everybody hails this innovation with delight, and there is a great clamor to have its use extended throughout London. Certainly nowhere on the habitable globe is such a contrivance more needed than here, where rain is the rule for seven months in the year, and where silk hats are insisted upon by the severest decrees of fashion and commercial usage.

—London Letter in *New York Times.*

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

INTERNATIONAL MEDICAL CONGRESS, BERLIN, 1890.

ON THE PRINCIPLES OF THE TREATMENT OF DIABETES MELLITUS.[1]

BY F. W. PAVY, M.D., LL.D., F.R.S.

THE first point to be considered in discussing the treatment of diabetes is the rationale upon which it should be conducted. A certain deviation from health, resulting in the escape of sugar with the urine, constitutes the condition that has to be combated, and something requires to be said regarding the nature of the deviation, before we are in a position to approach the question of how it should be treated.

The observable phenomena are that, whilst in the healthy subject the food ingested is disposed of in such a manner within the system as not to lead to the exit of sugar from it, in the diabetic subject the food fails to be similarly disposed of, but in part passes out as unconsumed and wasted material with the urinary excretion. It is with the carbohydrate principles that the faulty action lies. These, instead of passing in the direction that results in their consumption and utilization and thus disappearance within the system, as occurs in health, do not follow such a course, but remain in the state of carbohydrate, and are eliminated as such. The chemistry of the body with regard to these principles is at fault. The proper changes do not take place to lead to their being employed as they ought to be, and thereby lost sight of. Represented in other words, through defective assimilative action these principles do not pass on, it may be said, to their proper destination.

[1] From advance sheets furnished by the author.

Thus much is learnt by simply looking at the matter through the light of ingress and egress.

There is no theoretical consideration involved in stating that the carbohydrates in the system of the diabetic fail to undergo those right chemical changes which, in health, lead to their disappearance, and that consequently, whether ingested from without, or formed from the splitting up of nitrogenous matter within, they become disposed of by egress with the urine.

It may further, I consider, be stated that, as a result of the faulty action, the carbohydrate, in the form of sugar, reaches the general circulation in a manner it ought not. No one with any ground of support can contend that the sugar eliminated is formed by the kidney. Whatever appears in the urine has previously existed in the blood flowing to the organ, and osmosis suffices to account for the escape that takes place. I am of opinion it has satisfactorily been made out that healthy urine contains a certain small amount of sugar, and this stands in accord with what is observed as regards the condition of the blood under natural circumstances.

With regard to the presence of sugar in ordinary urine, I conducted a series of observations some years ago, in which I precipitated the sugar by means of lead acetate and ammonia, after previous separation of the uric acid by lead acetate alone. The compound of sugar and lead oxide was then decomposed by sulphuretted hydrogen, and the sugar estimated gravimetrically by boiling with the copper test liquid, collecting the precipitated cuprous oxide, and, subsequently, by the aid of a galvanic current, depositing the copper upon a weighed platinum cylinder. The amount found varied from .098 to .533 parts of sugar per thousand parts of urine.

The condition of the blood, as regards sugar, can be, with precision, defined by the application of the satisfactory analytical procedure which exists at our

command. There is no difficulty, with the exercise of proper attention, in securing the full extraction of whatever sugar is present in a given specimen of blood, and afterwards expressing its amount. From a large number of observations I may state that the quantity of sugar in blood taken under natural conditions does not amount to more than from about .5 to about .8 per 1,000. Under deviations from the natural state, the quantity may be quickly made to rise higher, and this, it may be said, should be borne in mind in looking at results where larger quantities are mentioned by investigators as having been found. I have made analysis of the blood obtained from persons suffering from diabetes, and have a record of seven instances. A general agreement is distinctly recognizable between the amount of sugar escaping with the urine and that found in the blood. Taking one instance where 751 grammes of sugar were eliminated with the urine in the twenty-four hours, the blood contained 5.763 per 1,000; whilst in another with 27 grammes in the urine for the twenty-four hours, the amount in the blood was 1.543 per 1,000. These are the examples giving respectively the highest and lowest figures of the series, both for urine and blood. It is correct to state that the condition of the urine as regards sugar affords an index to that of the blood. This is only what might be expected, seeing that the sugar is a diffusible substance, and that therefore in proportion to its presence in the blood so may it be looked for in the urine. As its presence to more than an exceedingly minute extent is abnormal to the urine, so the same may be said of the blood, and its presence in the blood to the extent occurring in diabetes means the existence of an unnatural state of this fluid, which induces a deviation from healthy action throughout the system. In proportion to the extent of this deviation from the healthy state—that is, in proportion to the amount of sugar reaching the general circulation and thence passing out through the kidney—so will stand the measure of severity of the symptoms of diabetes. Looked at broadly it may certainly be stated that the larger the amount of sugar eliminated with the urine, the worse in every direction is the condition of the patient suffering from diabetes.

We thus trace the symptomatic phenomena of the disease to the abnormal condition occasioned by the presence to an undue extent of sugar in the general circulation.

Whence, it may be next asked, arises this abnormality? I must not enter too far into the discussion of this matter; but the question has a distinct bearing upon the basis of treatment, and therefore requires to be touched upon to a certain extent.

I doubt not it will be conceded by all that the object to be attained by treatment is to diminish the deviation from health as far as practicable. It is only a rational procedure to endeavor to establish and maintain as close an approximation to the healthy standard as our knowledge enables us to effect. Observation shows that the amount of error as regards sugar in the blood, and, following upon this, sugar to be discharged with the urine, is in proportion to the amount of carbohydrate principles, of whatever kind, ingested. It may be said in general terms without, as I have already stated, asserting anything outside the region of fact, that the nature of the error to be dealt with consists in a failure of the power in the system to dispose of the carbohydrates in a manner to lead to their utilization and disappearance. But now arises the question, to what kind of faulty action is this failure to be attributed? Two points of view present themselves for consideration. We start with the fact that sugar is present in the blood to an extent that is unnatural. Is this due to sugar reaching the general circulation in a manner that it ought not? Or is it to be regarded as natural that all the sugar eliminated in diabetes should reach the general circulation, the error consisting of its not undergoing subsequent destruction, thus leading to accumulation?

It would be out of place to discuss these propositions here. The view to be taken rests on physiological considerations. It is known that I have over a long space of time given close attention to the matter, and my experimental inquiries lead me decidedly to affirm that I consider the source of the sugar encountered in the blood, and eliminated in diabetes, to be attributed to its being permitted to enter the general circulation in a manner that it ought not. This view harmonizes fully with the phenomena observed in diabetes. In health I would say the opportunity is not afforded for the ingested carbohydrates to appear in the urine, for the reason that they are not permitted to pass through the liver and reach the general circulation. In diabetes, on the other hand, we know that they do reach the general circulation in the form of sugar, and from the amount of this principle to be found in the urine it can be stated that they must do so in proportion to the amount ingested. I would therefore say that we have here to deal with a failure of power—assimilative or whatever else it may be called—to arrest the passage of carbohydrates through the liver. Being thus permitted to reach the general circulation, they are placed in a position to be discharged with the urine, and hence, according to the amount of carbohydrate principles ingested, so is the amount of sugar eliminated. With such a state of things existing, elimination necessarily follows upon, and is proportionate to, ingestion, and leads to the production of a result which is found to stand in harmony with observation.

I have spoken of ingested carbohydrate being checked by the liver from entering the general circulation as constituting what occurs under conditions of health; and I do not make this statement unsupported by the information afforded by experiment. I have conducted a large number of experiments upon the point, and can say from them that, when the requisite precautions are observed to obtain a representation of the natural condition of the blood of the systemic or general, and of the portal circulation, a large preponderance of sugar is encountered in the blood of the portal vein, if the observation be made a period of digestion and after the ingestion of food freely containing carbohydrate matter. But it is necessary to bear in mind, if the estimation of the sugar be effected, as is the common practice, with the copper test, that a fallacy may arise from the following circumstance, unless measures are taken to guard against it. With the transformation of starch in the alimentary canal preparatory to absorption, it is not, certainly to any noteworthy extent, carried higher than maltose, which, as is known, has a cupric oxide reducing capacity of sixty-one, as compared with glucose at one hundred; and much of it is only carried into a dextrin with a lower cupric oxide reducing power still. Hence the form of carbohydrate derived from starch, which reaches the portal system, does not possess the cupric oxide reducing capacity of glucose, but something more or less considerably below it. As an actual fact, I have a recorded instance in which the product contained in the portal blood after the

ingestion of starchy food possessed a cupric oxide reducing power standing as low as twenty-one, as compared with glucose at one hundred. In this instance, if reliance had been placed upon the ordinarily conducted method of estimation, the amount of carbohydrate present would have been expressed at only about one-fifth of what it really was. With a form of carbohydrate other than glucose existing, it is necessary to bring it into glucose by boiling with dilute sulphuric acid, to permit of the true amount being determined, and this has been the plan of procedure of late years adopted in the researches I have conducted.

I have considered it necessary to enter into these preliminary details. They display the nature of the faulty condition that has to be dealt with by treatment. Sugar reaches the general circulation in a manner that it ought not, and to its presence in the system are due the various symptoms belonging to diabetes. Through reaching the general circulation it becomes eliminated by the kidney, and is lost. The disease thus involves a sacrifice of material which ought by rights to be turned to account; but this is a point that has but little bearing on the production of the phenomena that are observed in connection with the disease. If it were only a question of waste of the carbohydrate principles of food, there would be no reason against their being taken and allowed to run off. Provided a sufficient amount of other alimentary principles were consumed to meet the requirements of life, no particular harm need arise from the sacrifice of the material occurring. What, it may be said, in reality inflicts the harm is the altered constitution of the blood, occasioned by the presence in it of the sugar which passes through the system to the urine. In proportion to the largeness of the amount of sugar thus traversing the system in the blood, so will be the extent of deviation from the natural state, and so in correspondence the impairment of health that will be found to exist.

The class of cases to which these remarks apply is that in which the discharge of sugar is susceptible of control by treatment, and the class embraces the majority of the cases in which the disease sets in after the middle period of life.

In such instances, starting with the indigestion of carbohydrate, there follows, briefly summarized, as a consequence of the want of proper transformation or assimiliative power within the system, an accumulation of sugar in the blood attended with its discharge by the urine. Accumulation of sugar in the blood leads to the production of symptoms proportionate in severity to the deviation from the natural state. The plain object before us is to reduce this deviation as far as is found to be possible.

We cannot be wrong in endeavoring to attain as close an approach to natural conditions as circumstances permit. If the chemistry could be set right, and sugar be prevented reaching the general circulation, the disease would be removed; but it may not be possible to restore the transformative or assimilative power which has become impaired or lost, and then the only way of arriving at what is wanted is to withhold from introduction into the system the alimentary principles which, owing to failure of power to properly dispose of them, cannot be of service, and which, by leading to the passage of sugar through the system, established an unnatural condition, and thereby inflict positive harm.

As long as the passage of sugar through the system is prevented no harm takes place. In the course of all my experience in diabetes I have never known anything serious to arise as a part of the disease so long as the urine has been kept from sugar. There is nothing, in fact, to form the source of trouble, seeing that there is not the abnormal presence of sugar in the circulation to occasion deviation from the healthy state. On the other hand, when sugar is passing through the system, and the remark applies in proportion to the amount passing through, not only are there to be observed the symptoms ordinarily consequent thereon, but a constant state of insecurity exists, from the danger of the supervention of the serious issues known to follow upon the disease. Moreover, with the unnatural state occasioned by the presence of sugar, nutritive action is not carried on in such a manner as to properly maintain the general strength. As a consequence, the general power becomes sapped, or prematurely exhausted, and the system weakened, and rendered less able to resist the effect of pernicious influences. Such is not the position when sugar is not similarly traversing the system. Indeed there is nothing to render the state essentially different from that ordinarily existing.

The contrast between the two conditions—that is, where sugar is allowed to abnormally exist in the system, and where it is prevented from doing so—is well shewn in cases where the disease has run on for some time without being recognised, and is subsequently controlled by dietetic treatment. What will be observed in such instances will be a gradually advancing impairment of health and increasing severity of the symptoms of the disease, and it is right to assume that progress in the same direction would run on, and the patient grow worse and worse, if the condition continued to be left to itself. Whilst matters are thus proceeding it happens, say, that the existence of the disease becomes recognized, and, if the case be such that the sugar is susceptible of being removed from the urine by the exclusion of the carbohydrate principles from the food, and this exclusion be carried out, this alone will suffice, not only to check the downward progress occurring, but to bring back health and strength to the patient.

The first consideration, therefore, in the treatment, is to control by dietetic measures the passage of sugar through the system. The real point, however, to be aimed at, is to restore the assimilative powef over the carbohydrate elements of food, and until this has been accomplished it cannot be said that a cure has been effected, but only that the disease is held in subjection and prevented, as long as the condition can be maintained, from leading on to an unfavorable issue. What most conduces to this desired restoration of assimilative power is the maintenance of a normal state of the system by keeping it free from the passage of sugar through it, and in this way bringing a healthy condition of body to bear in helping to promote a removal of the faulty state.

According to my own experience, opium and its derivatives codeine and morphine are the medicinal agents which, more than any others that I know of, assist in the actual cure of the disease, by which I mean a restoration of the assimilative power which has been impaired.

The influence of these agents may be witnessed in cases where the sugar has been brought down by diet to a certain point, but is unsusceptible of entire removal from the system by dietetic treatment alone. The complete removal may then be sometimes observed to follow the subsequent administration of the drug, shewing that the medicinal agent has acted in the direction of exerting a restraining influence over the abnormal production and elimination of sugar.

When cases of a favorable nature, that is, cases occurring above the middle period of life, are treated by those combined measures, and the treatment is steadily carried on for some time, it is a matter of common observation that the system of the patient becomes able to tolerate a certain amount of carbohydrate food, without its leading to the elimination of sugar. Often, with strict observance of the required treatment, the assimilative power is found to become so far re-established that a fair amount of the carbohydrate principles, or even an ordinary diet, may be taken without leading to the elimination of sugar. When this is the case, carbohydrate principles, according to the extent found to be tolerated, may be taken without occasioning harm; but the object is to keep below the point at which the escape of sugar takes place, and when this is done actual benefit, instead of injury, is derived therefrom.

Here I may refer to the aid afforded by the quantitative testing of the urine. It is absolutely essential, I consider, in the management of a case, to possess the knowledge thus supplied, not only for the purpose of regulating the treatment according to the progress made, but also for keeping a check upon the manner in which the directions given are being carried out. When in a case it is found to happen that the assimilative power has been restored, it is permissible to consider that an actual cure has been effected; but it is always requisite to bear in mind that a weak point has existed, and that it is advisable to avoid unduly taxing a power which has previously given evidence of being at fault.

FURTHER OBSERVATIONS UPON FOOT-AND-MOUTH DISEASE IN ITS RELATION TO HUMAN SCARLATINA AS A PROPHYLACTIC.

By J. W. STICKLER, M.S., M.D.,

ORANGE, N. J.

ON December 1, 1887, a paper upon the above subject was read in the presence of, and discussed by, the New York Academy of Medicine. Since that time I have obtained from Dr. M. K. Robinson, of Dover, England, additional statistics which he has secured for me at considerable personal inconvenience, and which are, I think, of sufficient interest to quote in connection with what has already appeared in relation to the matter under consideration.

First, let me review enough of my former paper to present clearly the subject as we are now to consider it.

During the early days of February, 1884, a remarkable outbreak of sore throat occurred in Dover, England, which was due to the drinking of milk obtained from cows affected with foot-and mouth disease. During the week ending February 9, two hundred and five persons were attacked with the disease. "The majority of persons who suffered during the Dover epidemic presented two prominent symptoms in common, viz., inflammatory sore throat and enlargement of the lymphatic glands;" but the lesions produced varied considerably in different cases. The vesicular eruptions were followed either by a raw, red, œdematous appearance of the mucous membrane, or white patches, and the ulcers which supervened, assumed in many instances a chronic character, with thick puckered edges, and were a long time in healing.

When the inflammation of the tonsils went on to suppuration, recovery was much slower than after common quinsy, and the enlarged cervical glands remained tender, red and swollen long after the throat symptoms had subsided, resembling, in this respect, the sequelæ of scarlet fever. (I am quoting now from Dr. Robinson's original paper on the Dover Epidemic). Erysipelas and purulent formations were concomitants, also, of the epidemic. "In some instances the feet of those who suffered were swollen and painful, simulating rheumatism.

"A fatal termination resulted in the cases of two children, who had very bad throats and mouths, with the extension of the disease, in one case, to the respiratory tract, their deaths being, in the opinion of the medical attendant, due to the poisonous effects of the milk." "Two persons who labored under chronic kidney disease, were respectively attacked with sore throats, and died on the same day; other people in the same houses suffering, also, from the 'epidemic sore throat.'" "A servant girl was attacked on February 4 with sore throat and pain in the limbs, complained on the 8th of great pain in the epigastric region, and dyspnœa. There was a purple red patch on the left cheek, extending to the nose. At 3 P. M. on the 9th she passed into a state of coma, and died at 4 P. M." "Mr. Wood says this was an obscure case, but thinks it possible that it was one of blood poisoning. Being in England in 1886 to investigate this unusual epidemic of sore throat, and wishing, if possible, to learn what relation, if any, it bore to scarlatina, I went to Dover to consult with Dr. M. K. Robinson. He received me very kindly, and said he would go with me to the various homes where the disease had existed, that we might gain the desired information.

The following *facts* were elicited:

1. That members of eight different families, who had previously had scarlet fever, escaped the "throat epidemic," while all the other members contracted the disease, all alike having partaken freely of milk infected with the contagium of "Foot-and Mouth Disease." The number of those who escaped was twenty-three +. I say plus twenty-three, because in the case of one family we were told that the father, mother, and servants escaped, the number of servants not being stated. Allowing the number of servants to be two, the whole number would be twenty-five.

2. That of one hundred and eighty-three persons who had the "throat epidemic," sixteen had had scarlet fever.

3. That four of the sixteen persons who had had scarlet fever, had a *mild form* of the "throat epidemic."

4. That two of the affected individuals had scarlatina *when young*.

5. That *none* of the persons affected with the "throat epidemic" had contracted scarlet fever from natural, accidental exposure, between the time of having the "sore throat" and the date of my visit (1886).

At this point, and in close connection with what has just been stated, let me quote, *in extenso*, the paper recently received from Dr. Robinson, the one alluded to in the first few lines of this article. It is as follow:

"DEAR DR. STICKLER.—I have at last been able to complete the further inquiry which you asked me to make, and beg to furnish you with the information sought for, which you may consider more complete than my previous communication to you upon the subject. The following summary has been compiled from statistics containing all the information procurable, concerning the epidemic of 1884:

Number of cases of foot-and-mouth disease which came under observation during an epidemic of this disease at Dover, England, in 1884.	Number of persons attacked who had previously suffered from scarlet fever.	Number of persons attacked who had *not* previously suffered from scarlet fever.	Number of persons who, having had scarlet fever and imbibed infect'd milk, *escaped* foot-and-mouth disease.	Number of persons who had foot-and-mouth disease in 1884, since exposed to scarlet fever without contracting the disease.
205	23	161	36*	14

"With regard to the prevalence of the disease in Great Britain it does not appear to have been worthy of recognition in our official nomenclature of diseases, and it has escaped notice by the leading authors of our text-books on medicine. When my interest in this disease, as developed in the human subject, was aroused, I had to resort to veterinary practitioners and veterinary works, in order to obtain descriptions of the symptoms and history of the malady. I am not surprised, therefore, that Sir James Paget should write to you, to the effect that he was not aware of the existence of the disease, when it fails to find a place in British nomenclature and teaching. It is now twenty years ago, when Medical Officer of Health for the Borough of Leeds, that a distinct epidemic of this disease came under my notice. It was confined chiefly to children who had partaken of milk from cows suffering from this disease, and the symptoms in the human subject were most characteristic. Since that time *limited* outbreaks have, from time to time come under my observation, which, although clear to my mind as to their nature and origin, were limited in point of number of cases on each occasion.

"Then came the sudden and widespread diffusion of the disease in Dover, which, with considerable labor, I was able to trace so clearly to its source that I felt it my duty to bring the matter before the medical profession and place on record the facts then elicited.

"When the history of this last-mentioned epidemic obtained notoriety from its publication in the daily papers, I had many communications on the subject from persons who had evidently sustained practical experience of the disease, but the nature of which had escaped recognition at the hands of medical practitioners. Thus Captain Reid, of Backsford House, Ashford, says in a letter to me: 'Some few years ago, whilst staying at a fashionable watering place, my children were poisoned from milk, which I ascertained for certain was derived from a cow suffering from foot-and-mouth disease. I at once recognized the disease, because on a previous occasion, five of my household had suffered from drinking the milk of a cow belonging to myself, which was afflicted with the disease.'

"Another gentleman told me that, being thirsty, he went into his cow-shed and drank off a glass of milk just yielded from one of his cows, which he found afterwards was ill at the time, and subsequently pronounced by the veterinary surgeon to be suffering from foot-and-mouth disease. This gentleman was attacked with bad mouth and throat.

"Another gentleman said: 'When my cows suffered from the disease, my man, along with his wife and family, would persist in drinking the milk from the diseased animals, and they were all attacked with the malady.' The Messrs. Crowhursts, veterinary surgeons, wrote me, saying that when attending upon animals suffering from foot-and-mouth disease, the attendants upon such animals had often complained of the same symptoms which were exhibited by the animals in question, etc., etc.

"The disease as it occurs in animals has been variously described as eczema epizootica, aphthous fever, epizootic aphtha, and murrain, and is characterized by fever and a vesicular eruption in the cleft of the hoofs, or in the mouth, with extension into the throat and nostrils. Shivering and a ropy discharge from the nose are often noticed at the onset of the attack. When the vesicles are ruptured, ulcers form, or red spots, bare of epithelium, appear, with the characteristic soreness which ensues.

"The incubation period varies; but animals have been known to suffer twenty-four hours after exposure to infection. Various complications occur, and erysipelas and pyemia have been known to supervene.

"The following characteristics were noticed in the human epidemic which occurred at Dover: Shivering, followed by headache and fever; pains in the limbs; thirst; parched lips, and a vesicular eruption on the throat and mouth. A common accompaniment was enlarged cervical glands; many had enlarged tonsils, in some instances proceeding to suppuration.

"In the *Veterinary Review*, Vol. iv, p. 502, and Vol. v, p. 187, will be found some evidence furnished by Dr. Balfour and Mr. H. Watson, on the transmission of foot-and-mouth disease by milk to man, and in the same periodical (Vol. v, p. 81) Mr. Hislop records some instances of human beings taking the disease by inoculation. Parkes, in his 'Practical Hygiene,' says: 'There has been much discussion whether the milk from cows with the foot-and-mouth disease causes affections of the mouth, etc., in human beings. There are some striking cases which seem sufficient to prove that diseases of the mouth, aphthous ulceration, general redness, diphtheritic-like coating and swollen tongue occur.' In the proceedings of the Royal Society for 1881 a new form of febrile disease is described by Dr. Evart, the propagating agent being milk from a dairy near Aberdeen.

"Gamgee, the eminent veterinary surgeon, says that the disease is communicable to man, as the history of the various outbreaks of disease undoubtedly prove. I have referred in detail to the above-mentioned symptoms as observed by reliable narrators, because I am satisfied that many ill-defined throat affections are due to bovine sources. During epizootic epidemics I have again and again noticed the concomitant prevalence of aphthous affections and diphtheritic-like appearances described often under the heads of follicular stomatitis and follicular tonsillitis.

"Dr. C. Fox described a peculiar epidemic, characterized by inflammation of the tonsils, extending into the pharynx, and sometimes to submaxillary and cervical glands, and accompanied by yellowish patches on the throat.

"This outbreak occurred in October and November, 1875, in a parish that differed from its neighbors in this: that the inhabitants were supplied with water from a stream polluted at various parts of its course by the drainage of farm-yards, the inference being that the specific poison was derived from the infected excretions of cattle.

"That some intimate relationship exists between scarlet fever and diphtheria appears to be extremely probable; my own view being that diphtheria can be produced by the pabulum on which the scarlet fever poison exists, during the interval between its passage from one human subject to another. I have known

* This number includes persons other than families in which the disease broke out, but who obtained the same milk supply.

instances where diphtheria has broken out at isolated spots in the country, when, after diligent search, no exposure to any previous case of diphtheria could be traced; but where I know that scarlet fever had previously occurred, and that those who suffered from diphtheria had been exposed to exhalations from scarlet fever infected excretions.

"Again, it is the custom in many parts of England to cart town refuse and garbage into the country, and there may be witnessed the disgusting spectacle of swine feeding upon the scavenger's motley collection, including, as such heaps do, not only decaying vegetable and organic matter, but rags and poultices from hospitals and sick-rooms.

"Many times has swine fever (which some maintain is allied to scarlet fever) broken out amongst pigs kept as above described, and I have also noticed that, in the same locality, the swine fever has been accompanied by foot-and-mouth disease amongst the cattle; but, what is far more important, human beings that have consumed milk from the infected cattle have suffered from diphtheritic-like affections of the throat. It is a striking fact that, in localities where foot-and-mouth disease has prevailed, there also has there been a large development of diphtheria or its congeners.

"The cases of foot-and-mouth disease officially reported in England increased from 37,000 in 1882 to 461,000 in 1883; and following this enormous increase of the epizootic disease there was a large increase in diphtheria. The number of deaths alone from this disease in England and Wales during the first quarter of 1884 being 1,270, and the death-rate from the malady higher than that recorded in any quarter of the previous fourteen years. The above observations I have not published; but you are at liberty to make any use of them you think proper.

"Believe me, yours faithfully,

"M. K. ROBINSON."

In immediate connection with this letter and the statistical table already given, let me call your attention to the facts concerning an outbreak of foot-and-mouth disease in Bethersden, England, in 1884. They are as follows, in tabulated form, namely:

No. of cases.	Age	Scarlet f'v'r previously.	Scarlet fever since.	Remarks by Dr. M. K. Robinson.
1	8	0	0	
2	10	0	0	Members of same family.
3	18	0	0	
4	6	0	0	
5	8	0	0	Members of same family. Four other members who had previously had scarlet fever escaped epidemic of sore throat.
6	5	0	0	
7	7	1	0	Same family — 7 and 8, mild sore throat, probably modified by previous
8	9	1	0	scarlet fever. (Dr. Robinson)
9	3	0	1	Very slight case of scarlet fever last year.
10	8	0	0	
11	2	0	0	Same family.
12	1	0	0	
13	9	1	0	
14	7	0	0	Same family. No. 13, mild case of scarlet fever. No doctor employed.
15	11	0	0	
16	9	1	0	Same family. No. 16, mild case of scarlet fever.
17	2	0	0	
18	12	0	0	
19	5	0	0	Same family. Three other members of this family who had previously had
20	4	0	0	scarlet fever escaped throat epidemic.
21	2	0	0	Same family. Case 22, mild throat
22	22	1	0	case.
23	6	0	0	
24	7	0	0	
25	7	1	0	
26	8	0	0	
27	6	0	0	No. 28 said to have been mild. No
28	9	1	0	doctor.
29	9	1	0	No. 29, mild throat case.

We learn from this table—

1. That two members of one family who had not previously had scarlet fever developed the foot-and-mouth disease, while four other members who had previously had scarlet fever escaped.

2. That three members of another family who had not previously had scarlet fever contracted foot-and-mouth disease, while the three other members who had had scarlatina escaped.

3. That but one person developed scarlatina after having had foot-and-mouth disease, and that attack was very mild.

4. That persons who, having had scarlatina, contracted foot-and-mouth disease, had the latter affection very mildly.

5. That these individuals developed the foot-and-mouth disease as a result of exposure to manure derived from cattle affected with aphthous fever.

As supplementary evidence in favor of the prophylactic power of foot-and-mouth disease against scarlatina, I will re-state the facts concerning three children whom I inoculated with the virus of foot-and-mouth disease.

CASE I.—M. M——, about eight years of age, had never had scarlet fever. On January 12, 1884, I injected, under the skin of his arm, a small quantity of virus taken from a cow having a mild attack of foot-and-mouth disease. A short time thereafter the cervical glands became enlarged and tender to the touch. There was no marked systemic disturbance, neither was there any sore mouth or throat. All signs of glandular enlargement and tenderness had disappeared in six or seven days. He was then taken to a house in which there was a boy sick with scarlet fever. The disease was in the desquamating stage, and the throat still sore. His parents being poor, the pillow upon which the patient lay had not been exchanged for a clean one since the beginning of the sickness. This pillow was placed upon the face of the boy who had been inoculated, and held there some time. He was then made to inhale the breath of the patient, and afterward to remain some time in the sick-room. The boy did not develop scarlatina after having been thus exposed, neither has he contracted the disease since, although there has been opportunity for infection.

CASE II.—B. P——, aged four years, had never had scarlet fever. On March 6, 1884, I inoculated her in the arm with a small quantity of foot-and-mouth virus. On March 13 her temperature rose to 103° F. Her mouth was sore without showing any vesicles, and she complained of a prickling sensation in her throat. She had slight headache, the appetite was impaired, and she was quite peevish. There was no eruption at any point on the body. By March 20 she was well. She was then taken to a house where I had a patient in the desquamating stage of scarlet fever. The patient was very sick at the time because of complications; indeed, was so ill that I was somewhat doubtful about the issue. The same plan of exposure was adopted as in the first case, except that I could not get the inoculated child quite near enough to the patient to inhale her breath; but the "pillow exposure" and the length of time she remained in the sick-room afforded a good opportunity for infection. She did not subsequently develop scarlet fever.

CASE III.—J. M——, aged about ten years, had never had scarlatina. I inoculated him just as I did the first two. He did not afterward develop any systemic disturbance or local lesion. After a lapse of three years, with opportunity for infection, he tells me he has not had scarlatina.

These cases, taken in connection with others, suggest gratifying results should further inoculations be made.

In one of my note books I find this entry, namely: "Thursday, August 19, 1886, went with Dr. Robinson to Canterbury, England, where we saw the health inspector, who told us that in one family the foot-and-mouth disease attacked *only* those members who had not had scarlet fever. We found four persons suffering from the epidemic sore throat who had had scarlet fever."

Without commenting now upon what has thus far been stated, I will describe, somewhat briefly (quoting Prof. Walley), foot and-mouth disease as it affects animals.

Synonyms.—Murrain, eczema epizootica, distemper, epizootic aphtha, vesicular aphtha, vesicular epizootic, aphthous fever.

Definition.—It is a vesicular eruptive, or exanthematous affection, due to a specific ferment, and having its lesions localized in the skin and mucous membranes.

Characters.—Eczema epizootica is probably indigenous in the bovine tribe only, but there is no direct proof that it may not originate in the ovine species also. It readily attacks sheep, goats, swine, and poultry; it is easily transmitted to the human subject, and it has been described as existing in the horse, the dog, wild fowl, deer, wild boar, etc. Walley says little or nothing is known of the ferment of this disease. Dr. Klein, of London, says the disease is caused by a micrococcus which forms in artificial media, besides dumb-bells (diplococcus), beautiful chains (streptococcus). These differ in length according to the number of micrococci composing them, the short chains being a linear series of four, six, or eight micrococci; the longer ones of more than eight up to thirty and more micrococci. The longer chains are always curved, and even convoluted.

In different outbreaks it localizes itself mainly in the feet, the udder, the mouth, the skin, and mucous membranes, respectively.

One attack does not give immunity from others; and not only may an individual animal suffer several times from it in the course of its life, but even twice or thrice in a season, though in the great majority of cases each successive attack becomes milder in its character. Dr. L. McLean, Government Veterinary Surgeon, says, "In the bovine species one attack of foot-and-mouth disease does not give immunity from the disease; but in the ovine species it does."

The channels by which nature endeavors to eliminate the poison are the salivary and mammary glands, the mucous glands of the bronchial and intestinal mucous membranes, and the skin.

The effects of the poison on the skin are invariably well marked, desquamation of the cuticle being extensive; but while this is a common characteristic of many zymotic diseases, it nevertheless points to the necessity of encouraging the elimination of the poison by this channel.

Period of Incubation is, compared with other zymotic affections, short, viz., from twenty-four hours to three weeks. The average is from two or three to five or six days.

Invasion is, on the whole, rapid and pronounced—the manner of invasion depending upon the amount of poison received into the system, the condition of the host, and the surrounding circumstances.

Duration is variable, and is regulated by the intensity of the attack and the care which is bestowed upon the patient; from ten to twenty-one days may be looked upon as the average period of duration where the disease runs a regular course, and is not succeeded by important sequelæ.

Fatality depends largely upon the character of the outbreak; in some seasons death in any animal is rare, while in others great numbers succumb to the primary effects of the disease.

Propagation.—It is propagated by direct and mediate contagion, as the virus is both fixed and volatile, but it is only diffused through the medium of the atmosphere at comparatively short distances. As the saliva, the nasal, conjunctival and intestinal mucous are highly charged with the virus, it is most readily spread by the conveyance of these secretions to healthy animals, by many direct and indirect means.

Symptoms and Course.—The symptoms must be divided in general, or constitutional, and local.

The premonitory constitutional symptoms are identical with those of other zymotic diseases. These are: Isolation, usually very marked; arched back in cattle; tucked up abdomen; muscular twitchings or shiverings, more or less severe; erection of the hair, the skin being hot and dry; and stiffness of gait, which is most pronounced when the feet—and particularly so if three or the whole—are affected.

Bowels usually a little constipated; urine sometimes scanty, high colored, and laden with solids, especially as the disease advances; at other times it is profuse and limpid. There may or may not be mucous discharge from the eyes and nose, with increased lachrymal secretion from the former. In young animals, exposed to inclement weather, such discharge is very constant, and in the course of a few days, that from the eyes forms a yellow accretion at the inner canthus of the lids and down the sides of the face, a similar accretion being formed, by the nasal discharge, round the edges of the nostrils.

Under exposure, an irritable bronchitic cough is present, by localization of the lesions in the bronchial mucous membrane.

Temperature always elevated to the extent of 2° or 3° F.; the pulse and respiration may not be much disturbed. Appetite indifferent when invasion is rapid, and the fever high, or the stomach and bowels affected; in ordinary cases, a desire for food is evinced, even though the lesions in the mouth are extensive. In ruminants, rumination is performed naturally, unless the mouth is much affected.

In milch animals, interference with the lacteal secretion will be largely regulated by the localization or non-localization of the lesions in the udder.

As the disease advances, the phenomena above enumerated, increase in intensity, and continue to do so until the climax—which may be calculated at from the third to the seventh day—is reached, after which they gradually subside.

In addition, vesicular and pustular eruptions may appear on the skin of different parts of the body; they are most often seen in the pig, and the primary may be succeeded by secondary and even tertiary crops.

Jaundice is a very frequent concomitant.

Desquamation of the cuticle is an invariable accompaniment of convalescence, the skin being covered with abundant bran-like scales of a yellow color; it is also extremely irritable, animals rubbing against prominent objects vigorously.

If the lesions are localized in the gastro-intestinal mucous membranes, colickly pains are induced.

The local lesions are, so far as the skin is concerned, usually seen in parts devoid of hair, or where it is delicate, as the feet, the mouth, the udder, and in

some cases the vagina of the female, and the sheath of the male. In all animals, the earliest pedal sign is lameness—more or less sudden and severe—with uneasy movements of the limbs. In the course of a few hours, subsequently to the advent of the lameness, the vesicular eruptions characteristic of the disease appears. The pedal vesicles are bladder-like elevations, varying in size from a hazel-nut to a walnut. If allowed to remain undisturbed, the vesicles burst in from three to twelve hours, and discharge a limpid, colorless, or pale-straw colored fluid; the jagged edges of the lacerated epidermis become retracted and slightly everted, and form an irregularly-raised white boundary around the margin of the resulting sore. The cutaneous structure, which is exposed by the eruption of the vesicle, is of an intensely scarlet color.

The advent of mouth lesions in cattle, is marked by smacking of the lips, or rather the mouth; by dribbling of the saliva, and by partial or total inability to masticate. The mouth vesicles vary in size and character, according to the part of the buccal membrane in which they are located. The pad vesicles appear as flattened elevations of the epithelium, without areolæ around their bases. On the tongue, the vesicles are much larger than elsewhere. They vary in number from one to five, and are very resistant. They present much the same character as on the pad. Two or three may coalesce and form one very large vesicle.

On the inside of the cheek, the reddened condition of the mucous membrane is more discernible, and the resistance of the vesicles considerably diminished.

On the lower lip, vesication in ordinary cases, is comparatively infrequent. The vesicles when they appear are much smaller. On the skin outside the lips vesicles are rarely seen. More frequently secondary than primary, are small, and succeeded by pustules and scabs.

In the course of a few days, the epithelium will be so far restored as to form a perfect coating over the inflamed tissues. In the cow, vesicles usually appear a few hours after the premonitory signs of the disease, on the body, and around the apex of the teats, but they may be developed in any part of the udder. At first they are discrete, but frequently become confluent. They vary in size from a three-penny piece upwards. The period of vesication will vary from one to two, to about thirty-six hours, depending upon amount of friction and pressure to which they are exposed.

The exposed epidermis, after rupture of the vesicles, is intensely hyperæmic, but if the parts are undisturbed, it quickly becomes covered by inspissated pus, coagulated lymph, and epidermic cells; the hair, when present, assisting in forming a coherent brown-colored scab which has usually irregular edges, and varies in thickness.

The substance of the tongue is usually much more flaccid than normal, and if the papillæ are carefully examined, it will be found that in the earlier stages of vasication, they are much congested, subsequently becoming atrophied and shriveled. It sometimes happens that when the tongue is seized, to explore the mouth, large patches of epidermis come away in the hand, as if the tongue had been boiled. This occurs in the aphthous stage when the vesicles have ruptured, and, the epidermis being removed, erosions appear. (Fleming.)

Thus far I have simply stated facts, such facts as should receive the most earnest attention of the profession. I make this statement without apology, because I am satisfied that when a disease failed to attack every member of eight different families who had previously had scarlet fever, and attacked every other member who had not had scarlet fever, there was some good reason for it; that reason apparently being—not coincidence—but the protective influence of one disease against the other.

Further, not only was this true of eight families in Dover, England, but of two families in Bethersden, England. Again, there were other individuals, who, having had scarlatina, escaped the throat epidemic, and, as already stated, when the throat epidemic occurred in those who had had scarlatina, it was mild in character, as far as could be learned; and, in the one instance in which scarlatina occurred after the epidemic sore throat, it was a very mild attack. Here, again, there must be some reason for the mildness of one disease when appearing after the other in the same individual.

Thomas, in his article on scarlatina, says: "Soon, perhaps already on the second or third day, the entire coating of the tongue, with the superficial layers, exfoliates either at once, or in successive sections, in a manner found in no other disease." Now, here is a disease (foot-and mouth disease), in which this very thing does occur, as already stated on the authority of Fleming. In both, the papillæ of the tongue are swollen and prominent; in both, there is abundant desquamation of the cuticle. Sometimes, in scarlatina, ulcers occur upon the tongue, cheeks, and gums, as in foot-and-mouth disease. Foot-and-mouth disease frequently attacks cattle more than once; sheep, on the other hand, do not so commonly have a second attack. In the case of scarlatina, Thomas (Ziemsen, Vol. 2, p. 186), says: "As a general fact, it cannot be disputed that scarlatina belongs to that class of diseases which occur but once; nevertheless, exceptions appear to be of comparatively frequent occurrence." He then says, he collected, in the literature to which he had access, about two hundred cases of a second infection, beside a few reports of a third and fourth infection in the same individual. Murchison observed relapses of scarlatina in two sisters. Trojanowsky says, "in two of his cases of secondary scarlatina, both parents had also the disease twice, and in a third case the father had been affected twice." Richardson states that he has experienced scarlatina in his own person three times. Sir Robert Gillespie tells of a young lady who had scarlatina three times, the diagnosis of which was unequivocal (Ziemsen, Vol. 2, p. 191). Henrici, during the epidemic of scarlatina in Kiel, from 1797 to 1798, attended a woman who was then undergoing her seventeenth attack of scarlatina with all its symptoms (Ziemsen, Vol. 2, p. 192). The latter statement may be exaggerated. Dr. Edward J. Ill, of Newark, N. J., writes me as follows concerning some of his own patients: "One of my patients, six years old, had an attack of scarlatina in 1881; in 1883, she had another attack; in January, 1887, a third attack; in 1888, she had a fourth attack. Desquamation followed in each instance." Another case: "J. G., aged twelve years, had scarlatina in 1888; had a prior attack in 1881."

The tendency to suppuration of the tonsils, and the continued enlargement of the cervical glands in persons who had the foot-and mouth disease, suggested a resemblance of the two diseases (scarlatina and foot-and-mouth disease).

A consideration of the above, inclines one to the opinion that the two diseases under consideration may be more closely allied to one another than has heretofore been supposed to be true, and that it is probable

that an individual who has had one disease, either will not contract the other on exposure, or will have it in a very modified form, if he contract it. Dr. Robinson, in a personal letter to me, says: "As to the prophylactic power of one disease against the other, my own view is, that if persons who have had one disease, and are exposed to the other, suffer from the alternate one, they do so in a mild form. If there is some intimate relation between the two maladies, it is fair, I think, to assume that persons who have suffered from one form are less susceptible to the other. I do not think I mentioned in my former communications, as evidence of the relation of the two diseases, that in the County of Norfolk, during a period of great prevalence of foot-and-mouth disease amongst cattle, in 1883, there was a great increase of scarlet fever, and especially a scarlatinal sort of sore throat. This fact was stated in the House of Commons during a discussion of the Contagious Diseases (Animals) Bill, on March 18, 1884, and reported in the daily papers the following day." Professor Law said, in discussing my former paper: "Epizootic foot-and-mouth disease had at times attacked nearly all the cattle and the people of Great Britain, and, considering the fact that the disease was so prevalent, there should be less scarlet fever in Great Britain than in America, where the foot-and-mouth disease is comparatively unknown."

Sir James Paget, in a letter to me upon this point, says: "I have not seen or heard of foot-and mouth disease communicated to persons in this country. I have asked some of those likely to have known of such cases if they had occurred, but I have learned nothing from them."

Professor Thomas Walley, of the Royal Dick'd Veterinary College, Edinburgh, Scotland, says in a communication to me: "Very few people contract eczema" (foot-and-mouth disease). Professor E. Klein, in speaking upon the same matter, says: "My dear Sir.—In answer to your letter of October 29, 1889, as to whether many of the people of Great Britain have had foot-and-mouth disease, I must say that during the nineteen years that I have resided in this country, I have heard of some outbreaks of foot-and-mouth disease amongst the people in various localities, but they were always localized and did not involve many cases. I must say that I have never been more surprised, than when you told me in your letter that Professor Law offered the remark that many persons in England have had foot-and-mouth disease. As a matter of fact, the contrary is the case. During the last four or five years, I have not heard of any appreciable amount of foot-and-mouth disease; in fact, I do not think there has been any epidemic of it. I have made inquiries of several friends in the country, and I hear from them that many practitioners have never seen a case in the human, in fact, some, in practice during the last four years, did not know it to have occurred in a single instance in their districts. Only a few weeks back I had a class in bacteriology, at which were twelve gentlemen, in practice as health-officers in various parts of England. Every one of them to whom I put your question, laughed at the idea that foot-and-mouth disease is alleged to be a common disease in man in this country." These gentlemen, evidently, do not agree with Professor Law upon the above point. Even if we assume that the disease is more common than it is supposed to be, such facts as are set forth in this paper concerning it, in its relation to scarlatina, have never been noticed or commented upon, and, to my mind, are not affected by the statement that scarlatina is very prevalent in Great Britain. Dr. J. Lewis Smith said, in discussing my former paper: "Since the time of Jenner, the hope has been awakened that some of the other fatal infectious diseases, and especially scarlet fever, might be prevented, as small-pox has been, by the inoculation of a milder and modified disease derived from the lower animals." Now let me ask my professional brethren, in a spirit of perfect candor and honest inquiry, if, in the evidence furnished by the epidemics in England, the facts concerning which are herein quoted. we have not a fairly secure basis upon which to build the hope that scarlatina may be either prevented or modified, by introducing into the human system, properly prepared and attenuated foot-and-mouth disease virus. Let me also ask if enough cases have not been quoted; a sufficient number of experiments performed; and the ultimate results of sufficient importance, to warrant a more extended trial being made of this proposed method of preventing the development of, or modifying one of the most fatal and dreaded diseases? No theoretical objection, however adroit and well planned, can settle the question before us; further actual experience with the diseases, in their clinical and apparently prophylactic relation to each other, must be had, before any one can positively deny, or prove to be true, that which seems to be a fact, namely, that scarlatina and foot-and-mouth disease are mutually protective.

Suppose some drug had been administered to certain members of eight families in Dover, England, prior to the appearance of the "throat epidemic," and that when the families were exposed to the contagium of the epidemic diseases, only those who had taken the drug escaped, while every other member contracted the disease. Do you not think that drug would have a new interest, and be given a fair trial, in order to determine, beyond disqute, whether it would, in the majority of cases, exercise this preventive influence? Now, why not, instead of saying: how can this be true? or this cannot possibly be realized—give the proposed method a fair, honest trial, just as you would give the drug a fair trial, or just as Jenner gave his method a trial, and then be guided in the future by the results. Suppose a certain number of children, in a children's hospital for the treatment of contagious diseases, were inoculated with a modified virus of foot-and-mouth disease, and after recovery from the effect of such treatment, should be put into a ward with scarlatina patients, and allowed to remain sufficiently long to be thoroughly exposed to the contagium of the disease, would not that be a fair way to settle the question? What I wish, is simply to determine positively, and as soon as possible, whether the escape from the "throat epidemic" of certain individuals in the two epidemics in England, and of the three children from scarlatina whom I inoculated with the virus of foot and-mouth disease, be due to the protective influence of the one disease against the other, as appears to be the case. If we learn that we may thus prevent the development of a disease so common, oft-times so fatal, and so frequently followed by distressing sequelæ, will we not confer a blessing upon those who are susceptible to its contagium? If, on the other hand, we discover that we cannot, in the majority of instances, confer this immunity, we shall at least have made a commendable effort to realize that, which a large number of clinical facts seemed to indicate as possible of accomplishment.

THE alleged case of cholera in London was undoubtedly one of cholera morbus.

RHEUMATISM AND ITS TREATMENT BY THE TURKISH BATH.[1]

By CHAS. H. SHEPARD, M.D.,
BROOKLYN, NEW YORK.

AT what time the disease called rheumatism first made its appearance is not known. The name was first applied in 1642, in a treatise on the subject by one of the most celebrated physicians of his time, M. Guillaume de Baillou, who was an author of several medical works of great merit.

No disease has proved more perplexing. Its uncertain course at times seems to baffle the physician at every point. Volumes have been written concerning its character, and other volumes still have been devoted to the various systems of treatment, which, from time to time have held the favor of the medical world. Nor is the subject exhausted. While much is unsatisfactory, and many new facts are continually discovered, opportunity yet remains for the investigator to discover more. Every new thought advances the welfare of mankind. It is the purpose of this paper to suggest some conclusions on the treatment of this disease which a somewhat extensive study, together with a practice of nearly thirty year's duration, have developed.

Rheumatism exists in three forms: the acute, the subacute, and the chronic. The prominent symptoms are well known. One most characteristic of acute rheumatism is inflammation, attended with intense pain in and around the joints, and with marked febrile and nervous conditions that indicate a disturbance of the nerve centers. Another noted symptom is the presence in the blood of an excess of lactic acid, which has a decidedly stimulant action on the cutaneous surface. Subacute rheumatism is a milder form of the same disease. Chronic rheumatism is a name which is loosely applied to many ailments not really of rheumatic origin. Properly speaking it is but a milder form of the subacute variety.

The pathology of rheumatism is acknowledged to be obscure, and consequently there is a great diversity of opinion regarding its essential nature. These different conditions are the expressions of but one morbid process with varying forms of intensity. At one time rheumatism was regarded as a general or an infectious disease; at another, as a fever; and again, merely as a peculiar inflammation of the joints and other structures. Of theories now in vogue, perhaps the most prominent one is that lactic acid accumulates in the body, and that the symptoms are directly traceable to the action of this poison upon the system. There is the nervous theory, the germ theory, and also the malarial theory.

Rheumatism is a constitutional disease, evolved in the system, the culmination of excretory products. The freedom from rheumatic symptoms immediately following a single attack, strongly indicates the expulsion of noxious matter from the system. As man is but the product of his environments, no valid claim can be made that any one cause is sufficient to account for all the disorder that this disease produces. It would be nearer the truth to call rheumatism the sum of all the transgressions of its victim. Lactic acid is a normal product of tissue metamorphosis. The morbid action which constitutes rheumatism gives rise to an excess of the acid, and this excess and the rheumatic symptoms both result from the same cause.

[1] Read before the American Medical Association, at Nashville, Tenn., May 30, 1890, in the Section of the Practice of Medicine.

It is reasonable to suppose that the special poison of rheumatism may find its principal obstruction while circulating through the tense fibrous tissue of the joints, and thus by pressure on the nerves of those parts, produce the pain characteristic of the disease. Retained excreta exercise two distinct actions, one, a stimulant action on the organ by which they are naturally eliminated, the other, a disturbing action on the tissues which supply the materials of their formation, and there is always danger from every arrest of the nutritive changes of the system.

Of the predisposing causes of rheumatism, one of the most important is that of inheritance, which can be traced in 27 per cent. of all cases. Some bring it on by overwork or exposure in damp or unsanitary surroundings. All nerve exhaustion tends to lower the vital reaction of the individual, so that a slight occasion often culminates in this disease; but in most cases the attack is induced by error or excess of alimentation. Indigestion is a frequent cause of rheumatism in the aged, and there is no doubt but that tobacco and alcohol are responsible for a large amount of this, as well as other disease. The action of tobacco on the nervous system, which is mistakenly supposed to be a tonic, is in reality only a toxic effect, and alcohol, by preventing the elimination of waste material, helps to aggravate every weakness and increase every predisposition to disease. These alcoholic drinks that contain lime salts are particularly injurious to rheumatics.

Rheumatic fever is simply a crisis, in other words a means of expelling morbid material from the system, and instead of trying to suppress it, we should aid nature in all her efforts to eliminate this poison. Disease, in whatever form it may appear, is but an effort of nature to free itself from some offending material in the system.

There is probably no disease to which so many different modes of treatment have been applied. Until about the middle of this century, bleeding was considered the sheet anchor in the treatment of acute rheumatism. Facts, however, tended to show that patients recovered more rapidly and satisfactorily when they were not bled, and the practice gradually was abandoned, for rhumatism as well as other diseases. Purgatives, diaphoretics, sedatives, and many other remedies have had their day. Then came the lactic acid theory, which naturally led to the alkaline treatment. Lemon juice also found favor for a time, with results quite as good as those from the alkalies. Of all these remedies, not one can be confidently relied upon. Indeed, it has been stated by good authority, that we have no remedy for acute rheumatism. Even the salycilates, salol, colchicum, iodide of potassium, etc., have proved a disappointment in many cases.

So unsatisfactory did all known remedies prove, that about thirty years ago some physicians gave up all treatment; simply kept the patient warm in bed, ordered a light, simple diet, and administered a placebo. Dr. Flint published in 1863 an account of thirteen cases treated on this plan with good results. Two years later Dr. Sutton, of Guy's Hospital, gave an equally good report of forty-one cases which were treated medicinally with mint water only. This expectant treatment was adopted by many, with results as satisfactory as those from more active measures.

For the treatment of a constitutional disease we must needs have a constitutional remedy, and this is furnished us in the modern Turkish bath. Having devoted over thirty years to the study of preventive

medicine, and having during that time been in an institution in daily contact with rheumatism, our opportunities have been exceptional. Of over three thousand cases of this disease under treatment, at least ninety-five per cent. have been either entirely relieved or greatly helped. Some who were treated over twenty years ago have stated that they have not had a twinge of rheumatism since. Under this treatment swollen joints have resumed their normal size, acute pains have been eradicated, and the patient restored to general good health. Men are to-day actively engaged in business who were brought to us by their physicians, who acknowledged that ordinary medication had failed to reach their case. The records of every establishment using this remedy will bear out the statement that remarkably few have persevered in its use without experiencing permanent relief.

It therefore needs no apology for bringing to the notice of the profession a remedy that has been almost invariably successful—and that is heat, the simplest, the easiest, and the most effective of remedial agencies. It is an important fact that we have perfect command over the blood circulation by subjecting the skin organism to the influence of artificial heat; and on this the whole sanative virtues of the bath depend.

This opens a new field, and offers results that are well worth investigation and trial. Every physician should know what a Turkish bath is, and acquaint himself with its practical workings. It is no new fashioned remedy of to-day. Its history dates back to tradition. We read of it in the early records of the Romans. In the Augustan period the bath flourished in its greatest magnificence. All the resources of science and art were made contributory to its completeness. When Rome overran Gaul and Britain, the bath attended her progress, and ruins of the splendid structures then erected are now to be seen in many places, notably at the Hotel Cluny in Paris and at the city of Bath in England. The success of the Roman armies was due in a large measure to the bath, which was to them the hospital and pharmacopœia. Traces of this bath are also found in ancient Mexico, in Ireland, and in many other countries.

For its modern revival we are indebted to David Urquhart, of honorable memory. He was an enthusiastic Englishman who had represented his country in Turkey, and there became enamored of the bath as an institution. One chapter of a book which he wrote, entitled "The Pillars of Hercules," and which was published just forty years ago, was devoted to the Turkish bath, and first called attention to the subject.

The Turkish bath of to-day is a most desirable resort, where all modern improvements have been brought into subjection for the comfort and enjoyment of the bather. Treatment by the Turkish bath immediately becomes a luxurious method of getting well. It is a sweating process, and heat is its vital principle. This can be used as high as 200° Fahr. and over in cases of emergency. It would be impossible for bacteria or disease germs of any kind to live in such a temperature, and it can be readily seen that with the circulation constantly coming under the influence of such an action, it would soon be purified and vivified. By this bath we can destroy personal contagion. This has been demonstrated in many cases. A few moments in the hot room brings a positive degree of comfort to the rheumatic patient, and soon so much relief is given by the heat that he will almost imagine that the disease has left him. Every pore of the skin is made an open sluiceway for the discharge of a large amount of perspiration, disease-germs included. The good effect of manipulation, which immediately follows, is intensified by this heated condition of the body. Certainly nothing can purify the internal and the external man more than this process, nor can any agency better assist the vital energies in the struggle against disease. The circulation is invited to do its most perfect work, and as the improved action of any organ only comes through a quickened circulation of the blood in that part, so we find that every function influenced by this natural stimulus quickly takes on a normal condition. When the body is thoroughly heated and the circulation most active, the reaction from a cold application is most agreeable and salutary. Inflammation necessarily implies a want of proper circulation. Some cause has plugged up the finer terminal blood-vessels of the part inflamed. A condition of stasis has been brought about. By applying heat we relax the tissues, so that the circulation can pass on and the offending material be thrown out through the usual excretory channels. Whether or not this theory be true, the fact remains that thousands have experienced entire relief by this process.

In ordinary treatment it is observed that while the rheumatic patient may complain of the unpleasant effect of the perspirations, he never complains of their weakening effect, such as is observed in hectic fever. On the contrary, he may describe them as bringing great relief to the bodily condition. The perspiration and increased circulation brought about by the heat are not at all exhausting or debilitating, for there is little or no drain on the vitality. There is an essential difference in this respect from the perspiration brought about by exercise.

That this bath is weakening, or in any manner debilitating, is thoroughly controverted by many facts, among others that the shampooers, who work in the heat several hours daily, never loose a day from its effects. On the contrary, they are examples of good health and vigor. Invalids, weakened by disease, and not able to sit up all day, have been subjected to this treatment, once and even twice daily, for months at a time, the result being a constant improvement in health, strength, and flesh. In fact, the more desperate the case, the more active and persistent the application of the bath treatment. Many trades find it necessary for their workmen to labor in a temperature considerable above 100 degrees Fahr., and the men are far from being injured thereby. Prof. Carpenter, in Human Physiology, endorses this same idea, and Chabert, the Fire King, was in the habit of entering an oven, the temperature of which was from 400 to 600 degrees Fahr. In fact, the whole weight of testimony disproves the notion that this bath is in any way enervating.

For those disposed to rheumatism, a careful and well selected dietary should be chosen. Sufficient only should be eaten, and that thoroughly masticated, the food being plain and simple. By a thorough regime of this kind, and a systematic course of treatment by the Turkish bath all may be freed from any liability to this most uncomfortable disease. Much has been and can be done by the practitioner in the way of expectant treatment, or the let-alone policy, by preventing the patient from injurious dosing or troublesome friends, and mainly by making him comfortable and simply assisting nature to throw off the disease as fast as possible. The cold bath has a wonderful tonic effect, but the greatest relief is

brought about by the sweating bath, followed by the cold dash. The change from hot to cold has an invigorating effect upon the nervous system, and this is in line with the Turkish bath treatment. A little ingenuity will often enable the physician to improvise what will answer the purpose for the time being, in the patient's own home. Wet compresses to the inflamed joints sometimes give great comfort. It is plainly impossible, however, in private practice to have all the facilities to handle this disease as comfortably, or to relieve as quickly, as in an institution where all these arrangements are made a specialty. Therefore, when it is practicable, it is advisable to at once remove the patient to an institution where the Turkish bath and its accessories can be secured. The advantages of medical care, proper diet, and the regulation of treatment to the conditions of the patient, by one who has experience in the matter, are desirable.

Out of the multitude of rheumatic patients that have come under our care, it would be unnecessary and not to the purpose to give the history of even a tithe of them. We have, however, selected six typical cases, simply to illustrate the treatment.

CASE 76.—H. W. W., aged forty one, was brought to the institution January 29, 1867, helpless from acute rheumatism, having been under regular treatment over six weeks. He was unable to move a joint in his body without much suffering, and was obliged to have an attendant sit up to help him turn over during the night. He was given one treatment daily, and for one week was carried to and from his room to the bath. After this time he could walk unaided, and he continued to progress till February 25, when he returned to his business, gradually taking on his full duties. He had then received but twenty treatments. He has religiously continued the use of the Turkish bath once every week since, and to this day, May 20, 1890, he has had no return of rheumatism.

CASE 84.—T. B., Jr., aged thirty-five, came to the institution, April 25, 1867, suffering from rheumatism partly developed. After two treatments, the rheumatism was so acute that he was unable to move without great pain, attended with high fever. After six days, during which he took two treatments a day, he was able to return to business, and has not been troubled with rheumatism since.

CASE 251.—C. R., aged twenty, a young German, was brought to the institution suffering with acute rheumatism, unable to walk or help himself. He was given two treatments a day, and for two days he was apparently no better; thought himself that he was worse; but in one week he was able to go up and down stairs without help, and in three weeks he left for home without an ache or pain.

CASE 2,248.—H. L. R., aged thirty-five. Case of rheumatism in right shoulder, reported that after the first treatment he had the best sleep of any time during the previous fortnight, and with daily treatment improvement continued to a quick recovery.

CASE 2,806.—W. H., aged twenty-one. A severe case of chronic rheumatism which had been under regular treatment for several months. Brought to the institution by his physician. He was anemic, and much emaciated, weighing but one hundred pounds, pulse 120, temperature 101° Fahr. Only able to take a few steps, with much suffering and pain, and that with the aid of a stout cane. There was enlargement of both knees and ankle joints, and he synovial membranes distended by effusion. After hree months he was restored to health, having taken two treatments daily, and gaining in that time seventeen pounds in weight.

CASE 3,375.—Mrs. J. F. Y., aged forty, was brought to the institution, helpless from a severe attack of acute rheumatism. Any motion of the limbs caused intense pain. After one week of daily treatment she was able to go to and from her room unaided, and improvement continued till at the end of two months she was in better health than she had been in for years before.

The one thing most prominent in the treatment of rheumatism by the Turkish bath is the fact that it works in consonance with every physiological law, and that it tends only to place the system in harmony with itself. When we secure a harmonious interchange and natural action of every function, we have the highest condition of health that the individual is capable of attaining. Inasmuch as rheumatism is all-pervasive and all prevalent, and the Turkish bath is its most perfect antidote, the more we spread the knowledge of its good work, and help to popularize and promote its general adoption, the more we help on the better time coming, by adding to the length of days of man.

Society Notes.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Special Meeting, August 19, 1890.

W. S. FOSTER, M.D., President in the Chair.

EXHIBITION OF SOME URETHRAL INSTRUMENTS.

DR. STEWART: The first instrument is the urethragraph. A year ago, last July, I exhibited my first urethragraph. I have made a number of changes. This instrument is for the purpose of recording a diagram of the urethra, giving the exact circumference at every point. The next instrument I will show you resembles the first one. It is almost the same in principle. It is for a different purpose; it is a combined urethrameter and urethratome, so made that it will either measure the urethra or cut a stricture. This instrument is inserted into the urethra as far as you may desire, usually to the bulbous portion. If you desire to cut a stricture, you first ascertain the size of the healthy portion of the urethra, the part you do not wish to cut, then permit the blades to open to the size you desire to cut. Having done this, fasten the screw on the upper surface and withdraw the instrument. The third instrument is the urethrascope, the fourth an urethral syringe.

DR. THOMAS: I have had no experience with the doctor's instruments. I did have a little experience in the doctor's presence with his first urethragraph. At the time it was not perfected, so that my experience will not serve in my remarks at present. The principle of the instrument is doubtless correct. I have been using the urethrameter of Prof. Otis, which I have considered the best in the market. The difficulty I found was this: that you had to cover the instrument with a gum tube, the gum tube always giving more or less resistance. After passing the urethrameter down as far as it would go to the bulbous portion, and then opening its arms to the full caliber of the urethra, then in withdrawing it when you would come to a stricture, of course the instrument would cease. Then, in order to pass through the stricture, you had to reduce the caliber until it would cut through the stricture, but in bringing it

through the stricture you could not tell where the stricture ended. You might pull your instrument anterior to the stricture. Now, that is the trouble with the Otis urethrameter. In the doctor's urethrameter, if the spring has the proper sensibility to come and go with the inequalities of the urethra, then it is a typical instrument. But the question is to me whether you can get a spring sufficiently graduated to come and go as you withdraw the instrument.

DR. STEWART: As Dr. Thomas has suggested, the spring in the instrument we used together was weak; this has been remedied.

DR. WERDER reported five laparotomies.

REPORT OF FIVE LAPAROTOMIES.

CASE I. Intra ligamentous cyst. Aged twenty-two years; epileptic; typhoid fever in October last, followed by bad health. Noticed a tumor growing since, reaching from one to one and one-half inches above the umbilicus down into the vagina, bulging out Douglas' *cul de sac* and pushing down the anterior wall of the rectum; in fact, almost completely filling out the pelvic cavity. The tumor was immovable, fluctuating, and distinctly pulsating both over the abdomen and in the vagina, suggesting the possibility of an aneurism. Exploratory laparotomy, March 29, exposed an intra-ligamentous cyst, which had to be peeled out of its capsule. It was a tedious and difficult task. Drainage. Patient made an excellent recovery, without rise of temperature and notable increase of pulse rate. Had an epileptic attack immediately after operation, then none for a week, though previous to operation she had a number of them every day. After first week they returned at intervals of several days.

CASE II. Pyosalpinx. Miss M. D., twenty-six years of age, had poor health for several years; about a year ago, she was obliged to go to bed, when an abscess ruptured into her rectum, which continued to discharge for several months. After the discharge had ceased, her health improved and she gained flesh, but six weeks later she experienced great pain in her right side, and when she entered the Mercy Hospital another abscess had ruptured into the vagina. She was extremely emaciated and anæmic. Laparotomy performed April 6. The anæsthetic used was the "mixture." Immediately after opening the peritoneal cavity she became asphyxiated. Respiration and pulse were arrested for fully five minutes; artificial respiration was performed, head and chest lowered, and hypodermics of whisky were administered. Probably ten to fifteen minutes passed until the respiration and pulse became normal and the operation could be continued. On introducing my hand into the pelvis, I found one large mass from which neither uterus, ovaries or tubes could be distinguished. After a great deal of trouble, I succeeded in freeing the right tube and ovary from their adhesions; both contained pus-cavities. The left tube was also removed with the greatest difficulty; its ovary, however, could not be found. A drainage tube was inserted. Twenty-six hours after the operation, a fecal odor was detected in the discharge from the drainage tube. The following day she commenced to discharge fecal matter in large quantities, and from now on most of her feces passed through the tube and on the sides of it, continuing to do so for a week. The wound was kept clean by enemata, which were immediately returned through the fistulous opening. During this time her appetite was poor, and vomiting very frequent, so that she became exceedingly weak. The fistula gradually closed up, so that at the time of her discharge from the hospital, there was only (sometimes at intervals of several days) a slight discharge of flatus. The occurrence of this fecal fistula can only be explained by the fact that the left tube, distended with pus, had become adherent to the rectum and discharged its contents through the latter. In separating this tube from its old adhesions to the rectum, the old rectal fistula, of necessity, was reopened, and, as a consequence, by virtue of the life-saving drainage tube, the fecal matter found its way through the external wound.

CASE III. Pyosalpynx. Mrs. A., three years married, aged thirty years, had one child at eight months, and was never in good health since. Had three attacks of pelvic peritonitis since; with the last one she was brought into Mercy Hospital. A very tender mass could be felt on both sides of her uterus, which was diagnosed as a double pyosalpynx. Laparotomy, April 29. Tubes and ovaries on both sides very firmly bound down to pelvic floor and adherent to loops of intestines. They were brought up with considerable difficulty and tied off. Ovaries on both sides were firmly attached to their corresponding tubes, each ovary and tube forming one abscess-sac. Drainage. Patient rallied badly from the operation, and vomited incessantly. She had taken ether very badly, a very large quantity being needed to keep her relaxed. The incessant vomiting was, therefore, attributed to the ether. It kept up for forty-eight hours; for thirty hours her pulse was about 160 and very feeble; had Cheyne-Stokes respiration, and an ashy color about her face. She was fed and stimulated freely by rectum, and forty-eight hours after operation she was much improved, her convalescence being then uninterrupted by elevation of temperature and with a good pulse; appetite was good, and she was sitting up in bed, when, on the evening of the twelfth day, a sudden change came over her; she complained of pain about the chest and of loss of appetite. Had shown symptoms of hysteria a day or two previous to this. I examined her carefully; her pulse was 100; temperature perfectly normal; abdomen flat without the slightest tenderness. She rested well during the early part of the night, but towards morning she became very restless, and died suddenly at 6 A.M. on the thirteenth day after the operation. A *post-mortem* examination could not be obtained. Her death was entirely unexpected and its cause very obscure, though I have reasons to suspect pulmonary embolism.

CASE IV. Solid tumor of right ovary and ascites. Mrs. S., aged forty-five, no children, consulted me about an abdominal tumor, situated on the right side of uterus, hard, irregular, freely movable, and reaching midway between the anterior superior spinous process of the ilium and the umbilicus. Lately she had suffered so much pain that she had to be kept under the influence of opiates constantly. The diagnosis was either solid tumor of right ovary or sub-peritoneal fibroid of uterus with long pedicle. Laparotomy, May 6. On opening abdomen a considerable quantity of ascitic fluid escaped. The operation was extremely simple, as there were no adhesions whatsoever. Patient made an uninterrupted recovery, the temperature never being above normal. The tumor, of the size of a large cocoa-nut, had become partly cystic and appears to be a fibroid of the right ovary.

CASE V. Abscess of left ovary. Miss Annie C., aged twenty-four years, had been in bad health for over a year. I was called to see her about a year ago, and found a large mass to the left of her uterus, not very tender to the touch, and fluctuating. She was greatly reduced in flesh and very weak. Under

treatment her general condition improved, but her local trouble remained the same, though local treatment was conscientiously employed for four months. I then advised laparotomy following my diagnosis of left pyosalpynx, but the operation was refused. She then placed herself under the care of another physician. Two or three months later, while going to her physician's office, on getting off the street car an abscess ruptured through her vagina, and this was followed by a severe attack of pelvic peritonitis. At this time I was again called in, and found the mass on her left side considerably larger and exceedingly tender. She was now very anxious to have the operation performed. Laparotomy, June 16. Removed a large ovarian abscess containing about a pint of pus. The sac was adherent to the omentum, intestines, anterior surface of bladder, and had to be peeled out; on doing this, the tube, firmly attached to it and to the pelvic floor, was broken off; the remaining portion was then brought up with great difficulty. The ovary was one large abscess-cavity, and the tube also contained pus. The right tube and ovary were, contrary to the usual rule, not removed, as the patient's condition was such as to make it dangerous to perform a second operation on her, especially as they seemed perfectly healthy. In breaking up the adhesions around the abscess-sac I accidentally ruptured it, and the pus poured freely into the abdominal cavity. This was thoroughly and repeatedly washed out with hot water, and a drainage tube introduced. Her recovery was uninterrupted; the temperature and pulse remaining perfectly normal, except on the day after the operation, when the temperature rose to 100. She is now in perfect health and has gained much in flesh.

DR. MACFARLANE:—It is gratifying to see so many patients relieved of tumors who do well. I do not say that it occurs in the hands of all operators, but very frequently the patient is left in a condition nearly as bad as that in which she was prior to the operation, the only effect being to prolong life for a time.

DR. WERDER: I will simply state that it is very unfortunate when the patient is left in the condition spoken of by Dr. MacFarlane. It is very important in performing a laparotomy not to make your abdominal incision larger than necessary. A small incision only is needed, not more than three inches. Now, if this is united very carefully, and the stitches put in at proper intervals, I think hernias will not occur very often, though they cannot always be prevented. In regard to fistulas, those are things that will often occur from septic ligatures. If you have not your ligatures absolutely aseptic, it is very likely that a fistula will follow, but with perfectly aseptic material, it should be a very rare occurrence to have a fistula.

CASE OF TYPHOID FEVER.

DR. KEARNS: A boy twelve years old, in the third week, ceased to speak even in monosyllables, and this condition continued for about ten days. During this time there was no apparent impairment of intellect. Sitting at the bedside of the patient and telling him to put out his tongue, he did it instantly. Telling him to look toward me that I might examine his eyes, he did it instantly. The pupils of the eyes were markedly dilated. Then, at the expiration of these ten days, the case assumed the very opposite condition, and became loquacious; he would take up any conversation which occurred in the room and follow it up repeatedly. This condition continued day and night, with some short intervals of rest for ten days, when it gradually stopped. The pulse was accelerated during this period of excitation. It was at a normal during the period of quietude. All this time the stomach had been in good condition. Now here are two extremes. What condition of the brain and nervous system is involved in these conditions of two extremes in the same patient and the same disease? This cerebral excitation was very difficult to control. The simple remedy, which appeared to have the desired effect, was calomel. I administered a gr. ¼ of calomel every two hours, then, when the bowels began to run off, in smaller doses. To me this was a very interesting case, and I ascribe the nervous symptoms to a complicating meningitis.

DR. THOMAS: During the month of April, I saw a patient with typhoid fever. The boy was thirteen years old. He had been sick about a week. The fever ran an ordinary course. About the twenty-first day there was defervescence, and I presumed the case was going the convalescence. I visited the boy as long as I remained in the city, and in the meantime he would not speak a word until the day before I went away, I got him to say one word. I did not feel uneasy about him, his temperature not being above normal. He went into the hands of Dr. McNeil. On my return, I found the boy all right, and was told that in speaking to his grandmother, in whose care he was, upon his beginning to talk again, the first word he said was cracker. He said, "Cracker, cracker, cracker," for three or four minutes; then he ceased calling for crackers. I looked upon it as caused by anæmia of the brain.

DR. STEWART: I remember a case where a man lost the power of the right arm. The loss was progressive, and then he had convulsions. The convulsions were in the arm affected. Subsequently they became general and he would become unconscious. The convulsions became very frequent, several times a day. An operation was performed under the supposition of lesion in that area. The man had had syphilis. Iodide of potassium had no effect on the case. The brain was uncovered and only a localized meningitis was found. Incisions were made into the brain and nothing was found. The man ultimately recovered the perfect use of his arm and had no more convulsions.

DR. MCKENNAN: I find that it is not at all uncommon to have peculiar mental states following typhoid fever—mental weakness, and also very frequently mental exhilaration. I have seen many cases of insanity which have been traced to typhoid fever. I have never seen a case of meningitis in a child with typhoid fever. The whole weight of authority goes toward the supposition that the lesion is purely of a functional character, and that there is rarely any structural lesion, although some authorities state the possibility that there may be embolism, which could only involve one artery.

DR. LANGE: No matter what cerebral symptoms we may have in typhoid fever, there is no justification for the assumption of meningitis. No matter how violent or how peculiar are the cerebral symptoms, the assumption of meningitis is not correct, is not justified. I do not know that meningitis and typhoid fever are incompatible; but I mean to say that *post-mortem* examinations in cases of typhoid fever which presented most violent and most strange ataxic symptoms have so invariably proven the absence of meningitis and of all inflammation, that such symptoms cannot be correctly assigned to meningitis or to any structural lesion, but are to be considered only as the toxic effect of the typhoid fever

poison. Neither can I understand how the speech center can be affected by a meningitis without previous and greater injury to the motor areas, which, being in closer opposition to the meninges than the center of speech, would primarily and to a greater extent be subjected to meningeal pressure. For this reason, paralysis is as common in meningitis as aphasia (barring, of course, comatose cases), is rare.

The Polyclinic.

MEDICO-CHIRURGICAL HOSPITAL.

FOR SUBACUTE CONJUNCTIVITIS.

℞.—Zinci acetatis..... gr. ss.
Aquæ dest..... ℥j.—M.

Or,

℞.—Zinci sulphatis ..... gr. ¼.
Acidi borici ..... gr. x.
Aquæ dest..... ℥j.
M.—S. Use freely, three times a day.

Apply vaseline to the edges of the lids at night. The former seems to act better in warm weather.

—*Fisher.*

FOR A CASE OF HEMOPTYSIS.

This was a large, well-nourished man, covered with prickly heat, and dripping with perspiration. Several bronchial hemorrhages had occurred within a week, followed by slight fever. He was ordered to abstain from liquids, to take a few drops of phosphoric acid to relieve thirst, and apply flying blisters to the chest. Internally he was given Gardner's syrup calcium hypophosphite, a teaspoonful four times a day.—*Waugh.*

FOR UTERINE HEMORRHAGE.

℞.—Ext. cannabis Indicæ..... gr. viij.
Ext. ergotæ fl..... ℥j.
Ext. hamamelis fl..... ℥ss.
Tinct. cinnamomi..... ℥ss.
M.—S. ℥j every three hours.

—*Montgomery.*

ASTHMA.—This patient's paroxysms are preceded by sneezing. There is some hypertrophy of the nasal mucous membrane. He sweats profusely and is tormented with constant thirst. This renders him sensitive to every breath of air; and demands first treatment. He is directed to drink nothing but hot, weak tea, a tablespoonful every hour; all other fluids being interdicted, except a small cup of tea after each meal. The nasal affection is treated by the application of chromic acid, liquid vaseline with one grain to the ounce; and he is given this:

℞.—Tinct. belladonnæ . . . . . ℥ij.
Ext. grindeliæ robust. fl. . . . . ℥j.
Tinct. hydrastis, ... q. s. ad . ℥iij.
M. S.—℥j. thrice daily.

—*Waugh.*

ABDOMINAL PAIN.—Three cases have come before me of constant, moderate pain in the abdomen, as the one symptom for which relief was demanded. The pain was of the same character in all; and the diagnosis only to be made tentatively. In the first, the course showed the pain to be due to caries of the vertebræ, finally causing death. In the second, death ensued, the cause being ulceration of the vermiform appendix with consequent perforation. The third case is before you; and here the pain is due to constipation, with impacted feces; vesical paresis is also present. He has been taking elixir of cascara sagrada, and compound syrup of hypophosphites; and using a hot enema whenever the pain became severe. So much relief has been experienced that he is confident of a speedy cure.—*Waugh.*

PHILADELPHIA HOSPITAL.

CLINIC BY E. LAPLACE, M.D.

GENTLEMEN: This little patient was brought into the hospital one month and a half ago, with a compound fracture of the tiba and fibula in the middle third. The wound in the skin was deep and was infected with dirt. It was, therefore, a double compound fracture, and, immediately after being taken to the wards, it was cleansed and put up in a fracture dressing permanently, as soon as possible after injury, and not disturbed until it was entirely well. There was a fracture, and therefore the indication was to replace it. There was a wound, and the indication was to sterilize it by removing all dirt and foreign matter, and cleansing with acid sublimate solution. In dressing the wound, we had to forsee swelling that would cause pain, and to meet it we applied sufficient cotton around the dressing to make allowance for it. The cotton yielded just as the swelling took place, and yielding did away with any pain. Having met these indications, this case had recovered under the *ideal treatment* of fracture. The leg was washed with acid sublimate and iodoform, put in and on the wound. The plaster of Paris dressing was applied to the leg, and the wound was left open. The plaster of Paris being applied, the wound was dressed with iodoform and sterilized cotton. The indications for dressing the wound were temperature and pain, for as long as there was no pain or fever we were sure the wound was doing well. This dressing remained in position for one month and a half, and when removed the bones had united perfectly, and the wound had healed without one drop of suppuration. The wound was never looked at from the day it was put up, even though it was a compound fracture of the lower extremity.

TUBERCULOSIS OF THE ANKLE.

Here is a case about which I have often talked to you. Here is a man, who has been apparently well all of his life; who sprained his ankle and has had a great deal of trouble resulting from it. In place of progressing as nicely as such cases generally do, it was noticed that the swelling would not subside, and that there was œdema, pain and fluctuation. We incised both sides of the ankle and removed a considerable amount of pus, which, when we first incised, was cheesy. That man had all his life the tuberculous diathesis, or tendency, and it only required a slight accident, that to us would amount to nothing, to develop tuberculosis that is present in the tendons and cellular tissue around the ankle-joint.

LUPUS.

The next case I bring before you is one of tuberculosis of the skin, or ordinary lupus. This case is highly interesting, from a diagnostic point. The woman has a double perforation of the palate, and, from her condition, as a rule, you will almost be disposed to diagnose it as a case of syphilis. Furthermore, she has had a miscarriage. This sore on her skin began three months ago, and came on gradually without any injury to excite its development. It is

purulent and the base is filled with rosy granulations. The skin and cellular tissue is affected, while at the apex of both lungs there is considerable consolidation with tuberculous matter. Notice the color, superficial condition and the tendency to dissect the skin, and is different from syphilis that ulcerates and burrows down into the tissues and has hardened edges.

TUBERCULOSIS OF THE EPIDIDYMIS.

The principal case I want to bring before you this morning, is one of tuberculosis of the epididymis—an affection that is very important from a diagnostic and therapeutic point of view. Three months ago this man noticed a lump in his scrotum. It has been his impression, all his life, that he had two testicles on the left side. Feeling the scrotum on the right side, it appears normal, but on the left it is different, for there are three enlargements. The top one is soft and fluctuating; the middle one is doughy and soft, and below is a hard mass, as hard as a stone. I might say that, until this morning, I was puzzled to know what this soft tumor at the top was, until I introduced an aseptic hypodermic needle and drew off a whitish fluid that had no spermatazoa in it on examination. It is a spermatic cyst. It is possible to have a spermatic cyst without spermatazoa in it. In dealing with tumors of the testicle, there are three great affections that almost stare us in the face—tuberculosis, cancer and syphilis. Generally, we must think of these three, and must prove, by exclusion, that it is one or the other. It is very easy to eliminate hydrocele and varicose veins. Inquire into the history, if he has had syphilis. This man did not have any of the signs of syphilis, such as eruption, sore throat or enlarged glands, and we can exclude it as the history is negative. This being eliminated, the next point to be considered is cancer. There is no hereditary taint or history; the tumor has come on in a short time, and was painful from the first, and became harder and harder, and took for its seat the epididymis, and I am sure it is not cancer. It must be tuberculosis. Why tuberculosis should attack the epididymis, we cannot explain, but 90 per cent. of the tumors of the epididymis are tuberculosis, especially in the head of it. Cancerous growths develop in the testicle and rarely attack the epididymis, except secondarily. Fibromas have been found to develop in the epididymis, but not in its head. In the treatment of this case I simply cut down on the tumor, and, having done so, put the hemostatic forceps around the cord, and cut it below, and ligate the vessels. The tumors and testicles are removed, and the parts dressed with iodoform and ether; apply a continuous suture and drainage and the wound will heal kindly. The specimens are now before us for examination. The upper one is a spermatocele, the other is a hydrocele, and lastly, the other tumor is tuberculous, with a cheesy deposit in the very center of the hypertrophied epididymis.

CLIMATE AND DISEASE.—1. In tracing the connection between the weather and disease, the tendency is to go too far and ascribe to atmospheric conditions more of a causative influence than we can prove. Because a climate may expedite or inaugurate a cure is no inherent proof that a climate, even though it have the opposite atmospheric conditions, will, *per se*, cause the disease.

2. Climate means more than the weather, and includes data concerning the contour of the land, the situation of hills and forests, and the nature and chemistry of the soil.

3. With no reason can we measure a climate by its absolute humidity alone, or ascribe to absolute humidity the supreme control over the origin of disease. Coincidence of data does not necessarily show a causative relation.

4. The degree of absolute humidity is more a resultant than a cause of atmospheric conditions, although it may be frequently a mediate cause of atmospheric changes. In no way, however, can we measure the value of absolute humidity, or discuss its influence upon our bodies, until we bring it into relation with something beyond itself. We are, therefore, constantly discussing relative humidity—if we use the English language with its proper meaning.

5. To assume that the weather controls health and causes disease by its influence upon the respiratory organs alone, is utterly to ignore the vascular and secretory systems of the body with their important functions. The assumption being unwarrantable, all conclusions and inferences based upon it are illusory.

6. *Absolute* humidity, *per se*, can have no influence upon health. Its influence depends upon the temperature and accompanying atmospheric conditions. A low absolute humidity in *cold* air is the mediate factor in abstracting *heat*, not moisture, from our bodies. A low absolute humidity in *hot* air will abstract moisture from our bodies proportionate in amount to the degree of relative humidity in which our bodies live.

7. *Relative* humidity measures the moisture absorbing powers of the air, is an expression of our surrounding atmospheric relations, and is modified by, and gives us a working notion of, the direction of the winds, and, at times, of the amount of sunshine. It represents conditions that are necessary to health and essentially local in their nature. It is, therefore, of great value to the physician.

8. The best single datum to be used with the temperature is the *dew point*, since in combination with the temperature it will enable us to determine both the *absolute* and the *relative* humidity. Definitely given, also, the amount of sunshine or of cloud, we can form a fair idea of the hygienic value of a given locality to health.

9. Condensed moisture has a great influence upon health. In some of its phases it is equally as important as humidity (aqueous vapor). When in the form of mists, exhalations, and fogs, it has, unfortunately, often been confounded with humidity.

10. The chief atmospheric conditions modifying health, and therefore causing disease, are sudden and violent *daily ranges in temperature*, and secondarily *in relative humidity*.

11. The *barometer* is an important but too frequently neglected instrument. A single observation of it gives us nothing that is of true value until it has been compared with preceding and succeeding inspections. The barometer should, then, be in a physician's office for daily use, and not for mere display.

12. We know, beyond doubt, the influence which certain low and wet localities exert upon health, but we do not understand completely the Why of this influence, so that we are not yet able to formulate with precision the general law under which our empirical observation is a particular instance.

13. I venture the prediction that when in future years our knowledge of the electricity of the atmosphere is more completely studied, we shall find in that mysterious force some solution of this problem. But I spin no gauzy theories upon the subject.

THE NEED OF A HOSPITAL AT SITKA.

ALASKA, our remote northern possession, is in various ways attracting a considerable share of public attention. While the protection of the seal fisheries constitutes a national problem, other questions directly concerning the interests of the natives of that region demand the consideration of the press and the people. The urgent need of educational facilities has, to a certain extent, impressed itself upon the public, but the necessity for the establishment of efficient medical service is a matter not generally understood.

An editorial in the Sitka *Alaskian*, of August 9, comments in a corroborative manner on a paper by Dr. W. F. Arnold, U. S. N., in the *Southern Practitioner*, on Sitka's Sanitary Status. Much practical information is given concerning the lamentable physical condition of the Indians of Alaska, and the necessity for the amelioration of that condition and the relief of the suffering aborigines.

Alaska contains a native population equal to one-fifth of the total number of Indians cared for by the Government. Two million dollars is annually expended for the support, education and sustenance of the Indians in the United States, while those of Alaska receive only a paltry appropriation of twenty thousand dollars, towards the maintenance of a few industrial and boarding schools established and supported by religious bodies.

It is true that the Alaska Indians and Esquimaux are self-supporting, but that is no reason why they should not be afforded an opportunity to improve their physical condition, which, at present, is a disgrace and discredit to the Government, and will eventually lead to their extermination. Large hospitals should be erected and liberally supported, in order to stamp out the frightful contagious and infectious diseases; caused more by ignorance than arising from vice, such diseases being prevalent among 75 per cent. of the Alaska tribes.

The Government having neglected the welfare of her newly-acquired possessions, and disregarded all recommendations and protests in behalf of these suffering people, the editor of the *Alaskian* hopes for good results in the way of reform, from the circulation of such papers as that written by Dr. Arnold.

Wherever a portion of the earth is penetrated by civilization, missionary efforts are established in behalf of the native population. The mandate to convert all nations is not left to the slowness of government legislation, but takes individual form and promptness. While the Prophet of Nazareth preached salvation of souls, he healed diseased bodies, establishing an example for true benevolence. Among the millions of those who profess to exercise the spirit of loving kindness in this great land, surely there is a fountain of charity ready to send forth healing waters for the diseased Alaska Indian. The hospital stands beside the chapel in foreign mission stations. Shall our own Territory be lacking in this feature? With the crowds of physicians and nurses annually issuing from our colleges and hospitals, and the ever responsive liberality of our people, must the endowment of a suitable hospital in this locality be left for national consideration alone? The story of the Indian has been a blot on the pages of history which should not be repeated.

UNSANITARY SCHOOL BUILDINGS.

SEVERAL months ago the Philadelphia Board of Health made a tour of inspection among the public schools of this city, with a view of ascertaining their sanitary conditions. The result was that seventeen schools were found to be unfit for use, on account of bad drainage, filthy closets and urinals, and other unsanitary conditions. At that time the Board requested that these schools should be "improved and repaired for the benefit of the health of the school children." Eight of these schools have been put in order, although it is still claimed that danger exists in some. The nine remaining schools have not been touched. They harbor, in all, 7,450 children for the best part of the day, in an atmosphere that cannot be other than disease-breeding. It is now rumored that if these buildings are allowed to remain as they are the Board of Health will declare them public nuisances, and order them closed. While such a procedure would throw nearly 7,500 children out of school, still this would be far better than for them to be confined for hours in such a dangerous building.

What is most conducive to a child's health is plenty of fresh air. Robbed of this, the constitution becomes enfeebled and undermined, and an easy prey to the diseases of childhood. Again, even when every precaution is used, children sickening with contagious diseases will be found in schools. Where the ventilation is good, the drainage efficient, and the closets sweet, the danger of contagion is infinitely lessened; but where the drainage is imperfect and the plumbing bad, the closets will soon become stopped up, and the exposed germ-laden excreta will not only vitiate the atmosphere, but may prove a source of actual contagion.

While we heartily commend the prompt action the Board of Health has taken in this important matter, we also see that their power is limited, and that they can only suggest and advise, and it is to be regretted that the Board of Education, after having been fully aroused to the gravity of the situation, has not done more to remedy the evil.

Annotations.

MEDICAL editors should make it a rule never to publish second-hand abstracts; but to limit their reproductions to abstracts from the original articles. Only in case of some item of undoubted practical value, which in the original form has escaped the eagle eye of the editor, should this rule be broken. For want of it, we see the parasitic journals, which are wholly made up of cuttings, credited with matter to which they have only the pirate's title. And, sometimes, the editor forgets that he has already seen an item, and republishes one as stale as the long-since exploded story about Drumine; which is actually resurrected by a Western journal and republished from it by another in the South. Usually both these journals are distinguished by the freshness and excellence of their selections.

BALLOONING OF THE RECTUM.

IN the *Lancet*, Burghard summarizes fifteen cases of this condition, first described by Bryant in January, 1889. This consists of an extreme dilatation of the rectal walls, so that the examining finger enters a large cavity, the walls of which have to be sought. Bryant stated that this condition exists only in connection with stricture of the rectum in its upper part, or of the sigmoid flexure. Of Burghard's cases five were associated with stricture (two as yet not confirmed by autopsy), two with fecal obstruction, and five with chronic constipation; two with spinal fracture, and one with extreme angular curvature from dorso-lumbar caries.

The cases of constipation were in old people, the youngest being forty-five. Matthew Duncan describes a semi-paralyzed "pouched" rectum in a woman, leading to retention of feces. In these cases there was no pouching, though the folds of Houston stood out like shelves, and sometimes upon them rested fecal matter. The greatest dilatation was backwards, so that the rectal wall seemed to be fitted into the sacral hollow.

The factor necessary to produce this ballooning is probably a paresis of the muscular portion of the rectum, with loss of contractility, distension by feces, flatus or enemas. Some cases showed that the rectal walls were thinner than normal. There is some analogy with senile atony of the bladder.

SCHULTZE says that beer should be drank out of gold-lined silver mugs. Next to these comes tin, and then covered salt-glazed stone mugs. Lead-glazed mugs and glass should be excluded.

Linke, however, disputes these conclusions, and states that 20,800 liters of beer must be drank from the worst kind of lead-glass to take in one milligramme of lead oxide.

Until the matter is settled it is best to refrain from beer; or at any rate to refuse it unless served in silver, gold-lined mugs.

The Medical Digest.

JACOBSEN (*Lancet*) reports a case of puerperal eclampsia occurring six days after delivery, and ending in death. The convulsion, from which she never recovered, occurred just after the patient had had a hot vaginal douche, during which she complained of feeling a little faint. The convulsions were replaced by coma, and in this state she died in about ten hours after the first attack.

DENUCE concludes an account of his researches upon the etiology of tetanus and vaccination as follows: We may then consider these experiments as ended and definitely adopt their results. They show that vaccination with strychnine gives to animals a considerable resistance against the tetanic virus, and furnishes an argument of great value in favor of the theory proposed and defended by Peyraud.

—*Jour. de Méd. de Bordeaux.*

PILCHER (*Med. Record*) reports fifty-one cases of whooping-cough treated by bromoform, and pronounces it the best known remedy when properly applied. It must be kept in dark, well-stoppered bottles. If it turns brown it should not be given. For children under one year he gave two to three drops thrice daily; for those from two to four years old three to four drops three to four times daily. The doses were increased on the third day. The quantity required to effect a cure was from five to twenty grammes; the time, ten days to four weeks. The dose was given in a teaspoonful of water. The bromoform sinks to the bottom of the spoon.

GAUCHER recommends boric acid as a remedy for tuberculosis. For five years he has experimented with this drug. The toxic dose is one gramme per kilo; or one-thousandth of the animal's weight. Elimination goes on actively by the kidneys; also by the sputa. Experiments on animals show that boric acid given with the food prevents the development of tuberculosis. In consumptives who took a daily dose of 15 grains, there was a notable diminution of the expectoration, which was also more fluid; the lesions remained stationary and the general health was more satisfactory. The author thought that a drachm per day could be taken by an adult.

—*La Medicine Moderne.*

ADDISON'S DISEASE.—Caven, in the *Canadian Practitioner*, reports a case of Addison's disease, which presented the following points of interest:

1. The limited area of the so-called bronzing, which was confined to the face, neck, hands and wrists. There was absolutely none on the buccal mucous membrane, or on any other part of the skin except that mentioned. Some small pigmented spots were found on the one arm, but these the patient said were moles, and had always been present.

2. The conjunctivæ were yellowish, as in jaundice; not pearly white, as usually found in such cases.

3. The pigmentation of the lymph glands of the mesentery appears to be an unusual feature. This pigmentation showed on the outside of the glands and on section.

The supra-renal capsules were enlarged, containing bean-shaped caseous nodules. The sympathetic ganglia and nerves presented no affection to be made out by the naked eye. The patient had been ailing for five months.

ACUTE MYELITIS.—In the *Med. Bulletin*, Hopkins describes a case of acute myelitis, in a woman seventy-one years old. She first felt a pricking in the fingers and toes; the sensation extending over the whole body. Partial loss of motion followed, so that she could not turn her head or body, but could make some movements. The inspirations were slow; expirations short and quick; breathing 20 per minute; pulse 60, and weak. Slight fever. No headache. Pupils normal. Examination showed tenderness over the vertebra prominens, where slight soreness had existed for some time previously. General anesthesia. Deglutition impaired. No history of injury, recent or old. Mind clear.

Bromide of potash was given in small doses, with digitalis; with chloral at night. Improvement commenced in a few days, and at the end of a month she was able to walk about her room.

HYOSCINE.—Sohrt found that this drug caused acceleration of the heart, from depression of the cardiac inhibitory apparatus without any change in the blood pressure. He therefore thought there was no effect on the vaso-motor center. Pavloff, however, finds that it causes at first a slowing of the heart, from stimulation of the inhibitory apparatus, afterwards acceleration from depression coming on. This last stage is antagonistic to eserine. The blood pressure was always increased for a time, then fell to, or below, normal. Pavloff also found it somewhat retarded respiration, and lowered the electrical irritability of the cerebral cortex. Hyoscine also antagonizes the effect of pilocarpine on the saliva; it has no action on the temperature or on the reaction of the blood; it lessens the irritability of the brain, and slightly the perception of pain; but does not affect tactile sensation. The chief difference from atropine is the effect of hyoscine in lowering the irritability of the cerebral cortex.—*Lancet.*

TEISSIER recommends the following treatment of typhoid fever:

1. Morning and evening, a cachet of naphthol, six grains; with salicylate of bismuth.

2. Four cold enemas every twenty-four hours to induce diuresis.

3. After the evening cold enema, another containing a drachm of extract of cinchona, and 9 to 15 grains of quinine dissolved in infusion of valerian, as a tonic.

4. Lastly, a regime composed of about 10 ounces of claret, milk, and a little soup.

This treatment was employed in fifteen consecutive cases, not selected, some being very severe. But one died, of suppurative nephritis, at the end of the attack. In nearly all, when antisepsis was complete, as shown by the green urine, the fever fell gradually, albuminuria disappeared, the spleen lost its abnormal volume, the tongue became remarkably moist and the saburral coating fell off. Short and speedy convalescence ensued.—*La Medicine Moderne.*

ANTIPYRIN IN DERMATOLOGY.—At the last meeting of the Dermatological Society of Berlin, Dr. Blaschko reported the results of experiences with antipyrin in the treatment of various affections of the skin. The remedy was first given in a case of urticaria papulosa. The case was one in which several well-known remedies, including tar and naphthol, had been used without beneficial effect. Not only was the itching relieved, but a permanent and complete recovery resulted.

Blaschko mixed the powder with equal parts of sugar, and of this mixture he administered as much as could be taken at a time, to half a teaspoonful. When prescribing the drug for children, the following formula was used:

℞.—Antipyrin..... 5 parts.
Simple syrup..... 25 "
M. Sig.—One teaspoonful at night.

Also in simple urticaria antipyrin decidedly ameliorated the unpleasant symptoms, while it did not effect a permanent cure. In cases of nervous pruritus and prurigo, doses of from seven to fifteen grains, given three times daily, had most beneficial effects. The drug was similarly found valuable in pruritus senilis, pemphigus, and exanthema exudativum multiform. It also allayed the itching of eczema.
—*Wiener Med. Presse.*

INFREQUENCY OF SYPHILIS IN ENGLISH COUNTY PRACTICE.—Alfred Freer, President of the Birmingham and Midland Counties Branch of the British Medical Society, in a presidential address, speaks as follows of his experience with syphilis:

"I am old enough to remember M. Ricord's instructive and oft amusing lectures under the trees of the garden at the Hôpital du Midi, when he used to operate *sub die* early in the morning. At that time one could not help looking at the world through a syphilized atmosphere, and when I came to country practice, I found plenty of examples of the old scourge; but for many years past I have seen less and less of syphilis, so I suppose the nymph is beginning to take up residence more exclusively in cities and large towns; or, perhaps, she is shy of appearing before graybeards. Her prime exhibit, the true Hunterian chancre, on which the great Ricord used to expatiate so eloquently, has almost gone from my gaze. It is a matter for national congratulation that, owing to the improvement in habits of cleanliness among the people, if not to improved morality, this disease is far less virulent than formerly, even in our large centers." That syphilis is not a disease the physician is often called upon to treat is assuredly the case in Philadelphia; but we are not so sure that the affection is less prevalent than of old. Perhaps the enterprising retail druggist could throw some light on the subject.

OSTEOMYELITIS FROM PNEUMOCOCCI.—The pyogenic properties of the pneumococcus are to-day well known, and human pathology counts some cases in which this microbe has been considered the agent of suppuration. It has been often encountered in serous purulenta, especially in pleurisy; in the synovial membranes in suppurative arthritis, it has been found in a state of purity. As to the osseous tissue, the pneumococcus has been often found in mastoid suppuration, consecutive to otitis. Here the microbe passes to the bone by continuity of tissue with that first affected. But it may penetrate to the bone as it does to the endocardium and the meninges, by way of the blood. Recently, Netter and Mariage have seen the pneumococcus invade the foyers of multiple fractures, without external opening, and there excite suppuration. Leyden reported in 1885 a case of labor pneumonia, in which an abscess of the thigh developed; probably a localization of pneumococcus infection in the osseous tissue, through the medium of the blood.

Lannelongue reports the case of a child, seventeen months old, affected with an abscess involving

the whole right thigh and the articular cavity of the hip. The diagnosis was osteomyelitis of the upper end of the femur, with epiphyseal separation. The abscess cavity was opened freely, the pus evacuated, and some improvement followed; but the child died in one month of marasmus. On microbiologic examination of the diseased tissues, the microbes existing presented the characteristics of Frankel's micrococcus.
—*Le Bulletin Médecal.*

Operation for Bunion.—Dr. Fowler, following Peterson, of Kiel, in his operations upon tuberculosis of this joint, attacks the joint from the outside, cutting backward between the toes, loosening the great toe sufficiently to allow turning it backward alongside the inner border of the foot; wedge-shaped pieces are then sawn from the joint surfaces of the first metatarsal and the phalanx thus exposed. The pieces removed from under the bunion are joined by the internal lateral ligament, leave a **V**-shaped depression, and represent from a half to two-thirds of the articulating surfaces.

The advantages claimed by Dr. Fowler for his operation are:

1. Ease of access to the diseased parts and their complete exposure.
2. The incision is through sound tissue.
3. The external lateral ligament is cut, after which the toe falls readily back into good position.
4. The exostosis is removed (Reverdin).
5. Tenotomy of the extensor pollicis can be done through the same incision.
6. The abductor pollicis is not touched.
7. The scar is out of the way of future pressure.

The operation fulfils these essential indications so satisfactorily that it may seem superfluous to make any changes, but in studying the operation upon the cadaver, it seemed to me that the incision and the loosening of the toe injured, unnecessarily, sound tissue. I accordingly made a long incision on top of the joint to the inside of and parallel to the tendon of the extensor pollicis, dissecting off the tissues from the inside of the joint with the periosteum elevator, till the bony surfaces were well exposed, when I found I could easily remove the **V**-shaped piece from the joint with the bone forceps. The toe now came back into place.

The piece removed should include more than half of the joint surface. It can be made at an angle, leaving the larger portion on the under side, which gives a broad portion to tread upon.

I have operated thus on three joints with good results.—Hunter, in *N. W. Lancet.*

Influence of La Grippe upon Surgical Operations.—Verneuil presented a paper to the Academy of Medicine upon this subject. His conclusions were:

1. La grippe exercises a malefic influence upon wounds and surgical operations.
2. This is felt during the attack, and during convalescence.
3. It is especially manifested by a tendency to suppuration.
4. The pyogenic tendency is shown by the appearance of conjunctivitis, otitis, parotiditis, pleurisy, pericarditis, peritonitis, purulent arthritis, furuncles, isolated or multiple abscess, superficial or profound, orchitis, suppuration in organs diseased previous to the attack of la grippe, as ovarian cysts, hydrarthroses, cystites, etc.
5. The venous, arterial, and lymphatic systems spontaneously becamed inflamed, with gangrene, from emboli derived from endocarditis vegetale.
6. Analogous complications in surgical cases, as:
7. Suppurations of wounds; even surgical cuts performed antiseptically.
8. La grippe following an operation delayed the healing, re-opened the wound and brought suppuration. If the wound occurred during convalescence, in some cases cicatrization did not occur normally; in others, the traumatism brought back or aggravated la grippe.
9. Certain complications. In benign cases, marked fever; in broncho-pulmonary complications, an added intensity, perhaps causing death; in others, septicemia and pyohemia; in others, the wound inflamed, sphacelus even, and the margins erysipelatous or lymphangitic.
10. The possibility of la grippe must be taken into account when deciding questions about wounds. A brusque rise of fever in the course of a surgical case, should cause a suspicion of influenza.
11. Influenzal pyohemia is peculiar in that it occurs often spontaneously, the abscesses are fewer, they often contain pneumococci and other pyogenic microbes; rigors are usually absent, the fever does not oscillate so irregularly.
12. The termination in cure is less rare in influenzal cases. This renders the surgical treatment of these abscesses by incision, drainage and antiseptic lavage more hopeful.
13. The reciprocally injurious influence of la grippe and traumatism being demonstrated, surgeons should refrain from operating during this epidemic, except in cases of necessity; especially in affections of the respiratory tract.
14. Before operating on influenzal cases, their general health should be restored, and a tonic and restorative course employed, with internal antisepsis by means of quinine, naphthol, etc. Change of air would probably prove beneficial.
15. Influenza seems to accelerate the growth of tumors.
16. It also influences pregnancy and its sequels unfavorably.—*Bull de l'Acad. de Méd.*

Medical News and Miscellany.

Opium can now be legally produced in China.

Professor Duhring has gone to Bar Harbor.

Influenza has appeared again in Breslau. Where's that "wave" theory?

Professor H. Earnest Goodman has returned from the Berlin Congress.

Professor J. V. Shoemaker has also returned. He now speaks nothing but French.

The death of Dr. Herman Rooker, of Philadelphia, was caused by opium poisoning.

A typhoid patient in the Cork Hospital died from an overdose of paraldehyde—about 3vj.

Chiropodists smile gleefully as they hear that wooden shoes are likely to become popular.

Dr. Z. P. Boyer has been appointed Medical Examiner of the Reading Railroad in this City.

THE Parisian authorities have taken steps to have the cars which transport cattle disinfected.

THE city of Toulouse wants a university. It is feared, however, that her morals are toulouse!

ICELAND now has the influenza, which on former visits has proved more fatal there than cholera.

DR. M. L. HERR, of Lancaster, arrived on the City of New York from Liverpool, with his daughter.

THE Eastern Dispensary, of New York, pays its doctors $200 per annum, or about 33 cents per hour.

VIDAL recommends acetate of ammonia in scarlet fever, giving fifteen grains for each year of the age.

THE caterer who supplied the G. A. R. in Boston has been prosecuted for selling them adulterated milk.

CRESSON must be doubly delightful to the President and his family, after a summer at Mosquito Point.

DRS. EDWIN TOMLINSON, E. E. JEFFRIES, AND E. R. SMILEY were nominated last week for Coroner of Camden.

IT is reported that Provost Pepper and his son have both been attacked with a mild form of grippe in Germany.

DR. CHARLES W. BROWN has removed from Elmira, N. Y., to 902 Fourth street N. W., Washington, D. C.

EDINBURGH has 236,000 inhabitants, of whom 103,095 receive medical charity. The Scot is certainly canny.

DR. J. MCFARLAND, of the resident staff of the Philadelphia Hospital, has gone to Berlin for a special line of study.

IT is said that the Italian clergy, unlike those of France and the most part of England, do not object to cremation.

GARIBALDI'S widow is reported to be about to be married to Dr. Gabriel Tanferna, of the Naval Academy of Leghorn.

AUSTRALIA consumes 276 pounds of meat annually for each person, the United States 120, Great Britain 105 and Russia 48.

PROFESSOR W. S. STEWART addressed the Congress in German, and is detained in London until his jaw has been cured.

THE Vienna Society of Hygiene has begun a collective investigation to ascertain the factors contributing to longevity.

A NEW YORKER has ornamented all the projecting corners against which a man can run in, in his bedroom, with luminous paint.

THERE were treated at the dispensary of the West Philadelphia Hospital for Women, during August 131 cases; number of patients in hospital, 9.

S. QUALE, who recently died at Eau Claire, Wisconsin, left a wish, but no will, that his estate should be devoted to a hospital for cripples in Madison, when its value reached $1,000,000. His wife has made the desired disposition of his property.

J. E. BLANK and J. Batt, of New York City, were brought before Judge Patterson at the Tombs for practising medicine without a license.

DR. AND MRS. HUGHES, of Fortieth and Chestnut streets, have returned from Spring Lake, where they have been sojourning during the heated term.

From May 13 to August 11 there were, in Spain, reported 1,672 cases of cholera, with 834 deaths; of which 80 per cent. were in the province of Valencia.

ESMARCH states his belief that the proximity of cemeteries, and drainage water from them, have no influence in the spread of epidemics or contagious diseases.

DR. WETHERILL has discovered another imbecile being improperly treated at home; this time it is a woman who has been locked up fifteen years by her brother.

Dr. CHARLES P. GRAYSON, of 122 South Forty-second street, has returned to the city after an extended visit to Narragansett Pier and other New England resorts.

A FEMALE patient mysteriously disappeared from St. Agnes' Hospital, and the authorities have not been able to discover her present whereabouts, or how she got out.

M'LLE EVERAERT has been appointed Assistant-Physician to the Hôpital S. Jean in Brussels. This is the very first female staff appointment in any Brussels hospital.

MEDICAL INSPECTOR TAYLOR made a report last week upon the condition of some of the principal schools which had been declared unhealthy in a report previously submitted.

THE Italian government has proposed to France an international scheme of sanitary control for the Suez Canal and the Red Sea. The French journals sit down on the project at once.

AN oleoresin is now prepared from pumpkin seeds which is said to possess all the tænicide properties of the latter. It is not pleasant to the taste. The dose is half an ounce.—*Pharm. Era.*

TWENTY dealers in milk in Philadelphia are to be prosecuted for selling watered, skimmed and colored milk. They are all persons who have groceries, etc., and merely keep milk as a side issue.

HEART failure caused thirty deaths in Boston during 1888; forty-seven during the first nine months of 1889; forty-one during the last quarter, and sixty-three during the first quarter of 1890.

A PRIVATE letter from Dr. P. D. Keyser, who was commissioned by Mayor Fitler to examine the sewage systems of leading European cities, during his trip abroad, reports that his investigations have been very profitable.

THE custom known as the *couvade* exists in Guiana, where a traveler says that a male Indian refused to help haul the canoes, on the plea that a child must have been born to him about that time, and that any undue exertion on his part might do harm to the infant. It is probable that this belief exists in all countries, and that this beautiful solicitude for the welfare of the unborn babe is often mistaken for pure laziness.

DR. NORVIN GREEN, the head of the Western Union Telegraph Company, is a Kentuckian of giant frame, nearly seventy-three years of age. He was a practising physician in the early days of his career.

THE wholesale poisoning of fish in Miller's and Griess' race, Pottstown, Pa., was investigated by Dr. W. B. Atkinson, of the State Board of Health, who found the trouble came from a lot of diseased meat which had been thrown into the water.

THE demonstration of the use of Dr. Ward Cousins' antiseptic tympanic membranes at the British Medical Association is said by the *Journal* to have been very successful. These were described by Dr. Cousins in THE TIMES AND REGISTER this summer.

SHONGOLOWICZ describes the microbe of granular ophthalmia as a short bacillus, very difficult to stain. Gentian violet is the best stain. Different segments take the stain irregularly, and this has led observers to look upon it as a micrococcus in chains.

WE have investigated many newspaper tales concerning the burial of living persons supposed to be dead, and have not yet found one in which there was the slightest truth. We would be glad to know of any case coming under the observation of any reader.

FROM every quarter the doctors who have been summering are flocking home, hearty and jolly, ready to relieve those who have borne the burden during the summer heat. Now is the time for the latter to take the vacation, without which no one is fit for the winter's work.

ONE of the best ideas yet broached is that of utilizing General Hastings' splendid executive abilities by placing him at the head of the World's Fair. With such a man as Director-General, and the enterprise of Chicago to back him, there could be no doubt of success.

FICTION has been grafted on the medical science. Announcement is made of a book in England in which the cheerful subject of "Diseases of the Liver" is worked into a "pleasant vein of fiction, thus combining useful knowledge on an important subject with all the charm of romance," as the prospectus puts it.

A LITTLE ripple of discontent was manifested by some of the nurses at the Philadelphia Hospital, on the admission of a colored pupil. To the credit of the girls, the feeling quickly evaporated. The new comer is a mulatto, from Oberlin College. She passed a creditable examination, and earned her admission.

GLEY had an opportunity to observe a man who was guillotined, within one minute after the knife had fallen. The heart beat for six minutes, the contractions of the auricles and ventricles being independent of each other. This is the first time in the history of science that such an observation has been made on a human body.

THE residents of Somerville, a settlement on the east side of Germantown, who send children to the Spencer Roberts School on Mill street, near Weiss avenue, are very much alarmed as to the future health of their little ones, if they use the water from the spring located outside of the school property on Mill street. The foundation of their fear lies in the fact that the spring will be fouled by the drainage from the wells of two outhouses now in course of erection, which stand about forty feet from the spring.

Lyada claims that yellow fever did not exist in Cuba until imported with slaves from Africa.

DR. DUNCAN MACFARLAN and about a dozen friends have been camping in the Adirondack Mountains, forty miles above Tupper Lake, for several weeks, and were very successful in both gunning and fishing. The doctor shot several bucks and does, and caught a large bear, and the whole party had a jolly, healthful, pleasant time, and returned much recreated.

DR. JUNKER, who learned in Central Africa to relish fried ants, and lived for years on a negro bill of fare, expresses decided views in his new book on the way to get along in the Dark Continent. He goes so far as to say that in his opinion the white man who accustoms himself to native food will keep in better health than if he enjoyed the best of European cookery.

THE laboratory of H. K. Mulford & Co. was totally destroyed by fire last week, and, unfortunately, was only partially insured; however, they are at work again, and the retail store, which was fortunately saved, has continued work uninterruptedly. It is a progressive firm composed of three young men, H. K. Mulford, Milton Campbell, and E. V. Pechin. They are prepared to fill all orders.

THE State Board of Charities held a regular meeting at the rooms 1224 Chestnut street, last week, with President Mahlon H. Dickinson in the chair. The other members present were Dr. J. W. C. O'Neal, of Gettysburg; Colonel H. M. Boies, of Scranton; Thomas W. Barlow, William B. Gill, and Cadwalader Biddle. Secretary Henry M. Wetherill, of the Committee on Lunacy, was also present on invitation.

IN using porcelain filters it is necessary, once a month, to open the filter, remove the porcelains, brush them well and plunge them for an hour into a mixture of five parts pure water with one part of commercial muriatic acid. They should then be rinsed in pure water, replaced, and the first quart of water filtered thrown away. If the water is muddy, this must be done twice a week. The Gate City stone filters should be brushed and rinsed every day.

NORTH DAKOTA has again approved her claims as the best place to emigrate from. In the preceding five years her record has been: three seasons the crops were killed by drought, once by frost in the middle of August, and the fifth summer the wind blew the wheat out of the ground. This season, what little grain had escaped mischance, was ruined on September 5 by hail, which broke the windows and drove the occupants to their cellars for shelter.

A VERY remarkable accident is described in the *Lancet*. An Italian vessel had in her hold a number of wine casks, into which sea water had been pumped to act as ballast. One of the crew opened the bungs to let out the water, when a stream of poisonous gas rushed into his face, and he fell back dead. Each of the other four men went down to the hold and instantly died. The gas increased until, when the captain looked down the trap-door to see what had become of the men, the rush of the gas overcame him, and he fell into the hold with the others. The only survivor of the crew called for help, and when the fumes had diffused so as to become harmless, the bodies were taken out. The accident is attributed to the action of the salt water, during midsummer days, upon the incrusted tartrates in the casks.

Dr. G. Betton Massey has removed his offices and sanitarium to 212 South Fifteenth St.

The hot water pump at a factory refused to work; and it was decided to take it apart; which meant a heavy loss from stoppage of work. Just then a genius in matters mechanical was summoned, who gave three raps on the valve with a hammer, and "she went." Next day the genius proved he was no genius at all, by sending in his bill for $25.50. The price amazed the payer, until he noticed that the bill read: "For fixing pump, $0.50; for knowing how, $25.00." He paid it at once.

The idea might be utilized by the doctors.

During the past few years the subject of hygiene has received marked attention from the German government. In nearly all the leading universities there are now hygienic institutes, thoroughly equipped in every way. Recently the new hygienic institute in the University of Halle was opened. The institute has a lecture-room, and also special chemical, physical and bacteriological laboratories.

At the banquet of the Surgical Section at Berlin, the menu was accompanied by a Latin ode, of which this is the first verse:

Beatus ille qui procul chirurgicis,
Securus inter epulas,
Hilariter maxillis exercet suis
Quæ mensa præbet munera:
Non minus fascinatus symphoniacis,
Jocose blandientibus,
Quam thyrso Bacchi raptus pampinifero,
Solutus omnino opere,
Neque excitatur osteogenesibus,
Nec jam resecto stomacho
Neque intestino abhorret intussuscepto,
Rectique vitat tenebras.

Hail stones.—The *British Medical Journal* states that Dr. Fontin, a Russian observer, has recently demonstrated the existence in hailstones of pernicious microbes or microscopic organisms. The water resulting from the melting of the stones used in the experiments yielded an average of seven hundred and twenty-nine bacteria to the cubic centimeter (a volume about the size of a small marble). Nine different forms of bacteria were discovered, including the bacillus mycoides. "As the abiding place of this bacillus is the earth, the fact that it and its pestilential congeners can be carried to the heavens and returned to the earth with hail, rain, and snow, and directly convey infection, is another of the discoveries which, while adding perchance to the glory of science, impress us with the blissfulness of ignorance, and also with the fact that in the midst of life we are in death."

Mississippi Valley Medical Association.—The Mississippi Valley Medical Association will hold its sixteenth annual session at Louisville, Ky., October 8, 9, 10, 1890. The medical profession is cordially invited to attend. The President is Dr. Joseph M. Mathews, of Louisville, Ky.; Secretary, Dr. E. S. McKee, Cincinnati, Ohio; Chairman Committee of Arrangements, Dr. I. N. Bloom, Louisville. Gentlemen having business with either of these gentlemen can correspond with them, and they will give desired information. The Association is the outgrowth of the old Tri-State Medical Association, which consisted of Indiana, Illinois, and Kentucky. It has now spread over that territory so fertile in soil and sense, the Mississippi Valley. The best men of the profession are on the programme. Among them are the following: Love, Ohman-Dumesnil, Mudd, St. Louis; Geiger, St. Joseph; King, Kansas City; Hollister, Lydston, Belfield, Chicago; Dunning, Indianapolis; Walker, Evansville; Reamy, Whittaker, Ransohoff, Thrasher, Ricketts, Lichberg, Cincinnati; Murdoch, Sutton, Daly, Wood, Pittsburgh; Scott, Vance, Corlett, Baker, Cleveland; Woodbury, Hare, Philadelphia; Wyeth, New York; Wile, Connecticut. The subjects cover every department of medicine and surgery. The efforts of the profession in Louisville to handsomely entertain their coming guests are on a magnificent scale, and none who go will regret having done so. The ladies will be given a pleasant time, and it is to be hoped that a large number of them will be present. To add to the interest of the occasion the American Rhinogloical Association will meet at the same place the same week, viz.: October 6, 7, 8, 1890. The Secretary is Dr. R. S. Knode, Omaha, Nebraska.

The American Association of Obstetricians and Gynecologists.—Programme of the Annual Meeting, to be held in the Hall of the College of Physicians, Philadelphia, Pa., Tuesday, Wednesday, and Thursday, September 16, 17, and 18, 1890.

First Day.—Tuesday, September 16, 1890. Business Meeting at 9 o'clock A. M., for Fellows only. Morning Session, 10 o'clock. 1. Address of Welcome, by William F. Waugh, and Response; 2. Some Facts Relating to the Diagnosis and Treatment of Placenta Previa, Dr. James P. Boyd, Albany; 3. Adherent Placenta; its Causes and Management, Dr. Aug. P. Clarke, Cambridge; 4. Venesection in the Treatment of Puerperal Eclampsia, Dr. Thos. Lothrop, Buffalo; 5. The Relation of Albuminuria to Puerperal Eclampsia, Dr. Wm. S. Gardner, Baltimore. Afternoon Session, 3 o'clock. 6. Tincture of Iodine in Hyperemesis Gravidarum, Dr. Llewellyn Eliot, Washington; 7. Practical Teaching in Obstetrics in America, Dr. Geo. H. Rohé, Baltimore; 8. The Axis-Traction Forceps; its Place in Obstetrics, Dr. Joseph Hoffman, Philadelphia; 9. The Vectis; a Forgotten but Valuable Instrument, Dr. Wm. Wotkyns Seymour, Troy.

Second Day. — Wednesday, September 17, 1890. Morning Session, 10 o'clock. 10. A Novel Mode of Exit for an Ovarian Cyst; Report of a Case in which the Contents were Vomited after Perforation of the Stomach, Dr. Geo. R. Dean, Spartanburg; 11. The Surgical Treatment of Peritonitis; With a Report of Cases, Dr. Joseph Price, Philadelphia; 12. Some of the Difficulties Met with in Abdominal Surgery, as Illustrated by Cases Taken from Personal Records, Dr. A. Vander Veer, Albany; 13. Complications Following Laparotomy, Dr. Wm. H. Wathen, Louisville; 14. Annual Address of the President (12 o'clock M.), Dr. E. E. Montgomery, Philadelphia. Afternoon Session, 3 o'clock. 15. Ovarian and Ligamentous Cysts Coëxisting in the Same Patient; Operation; Death from Shock, Dr. Wm. Warren Potter, Buffalo; 16. The Elastic Ligature in the Extraperitoneal Treatment of the Pedicle, Dr. X. O. Werder, Pittsburgh; 17. Hydatids of the Broad Ligament; With Report of a Case, Dr. N. B. Carson, St. Louis; 18. Personal Experience with Gallstones and the Operation for their Relief, Dr. Wm. Wotkyns Seymour, Troy; 19. Report of a Case of Extirpation of Calculus from the Ureter by Combined Abdomino-Lumbar Section; Recovery, Dr. Rufus B. Hall, Cincinnati.

Third Day.—Thursday, September 18, 1890. Business Meeting, 9 o'clock A. M., for Fellows only. 20. Special Gymnastics in the Treatment of Diseases Peculiar to Women, Dr. John H. Kellogg, Battle Creek; 21. Report of Gynecological Cases Treated

with Electricity; With Remarks, Dr. Franklin Townsend, Albany; 22. Uterine Malposition and Disease as a Cause of Insanity, Dr. Geo. R. Shepherd, Hartford; 23. Infantile Vulvar Hemorrhage, Dr. Thos. E. McArdle, Washington. Afternoon Session, 3 o'clock. 24. The Treatment of Fibroid Tumors of the Uterus, Dr. L. S. McMurtry, Louisville; 25. A Further Discussion of Vaginal Hysterectomy, Dr. Chas. A. L. Reed, Cincinnati; 26. Presentation of Specimens; With Remarks on their Nature and Complications as Observed at the Operating Table, Dr. Joseph Price and Dr. E. E. Montgomery, Philadelphia.

NOTE.—Papers will be read by Drs. Myers, Marcy, and Branham, whose titles were offered too late for classification.

NEW PATENTS:—

PATENTS GRANTED SEPTEMBER 2, 1890

Ammonia-still	Stroh & Osius	Detroit, Mich.
Atomizer	G. Schlauch	Lancaster, Pa.
Making carbon tetrachloride	E. G. Scott	Port Sunlight, England.
Fumigator	L. Russell	Luling, Tex.
Insecticide	W. Mann	Fresno City, Cal.
Preserving compound	O. Williams	Milwaukee, Wis.
Vaginal tampon	C. C. Fredigke	Chicago, Ill.
Truss	Wells & Ewell	Rochester, Mich.
Veterinary surgical device	J. F. Van Ness	Gloversville, N. Y.

TRADE-MARKS REGISTERED SEPTEMBER 2, 1890.

Perfumery. (The words "Rhea Bouquet")	G. Mandelbaum & Co.	New York, N. Y.
Soporific. (The word "Somnal")	Eisner & Mendelson Co.	New York, N. Y.
Perfumery, toilet-waters, sachet-powders, tooth-powders, and smelling salts. (The words "Sweet Spray")	Ladd & Coffin	New York, N. Y.
Nerve foods, or remedies for nervous exhaustion. (The words "Peruvian Nerve Compound," with the word "Peruvian" extending upward at an angle in front of the word "Nerve")	Standard Medicine Co.	Boston, Mass.
Specific for Affections of the Throat, Chest and Lungs. (The words "Dr. Watson's New Specific," with the portrait of Dr. L. Watson)	Cumberledge, Garver & Deal	Carthage and Kansas City, Mo.

LABELS ISSUED SEPTEMBER 2, 1890.

"Follmer's Crystal Eye Medicine"	H. Follmer	Jersey City, N. J.
"Marshmallow Skin Soap"	The Diamond Laboratory Co.	Naugatuck, Conn.
"Cactus Balm Hair Grower"	J. W. Smith	Boston, Mass.
"Cactus Balm Skin Cure"	J. W. Smith	Boston, Mass.

PATENTS EXPIRING SEPTEMBER 2, 1890.

Hair wash	R. Travis	Elkton, Ky.
Medical compound	M. P. Munder	Baltimore, Md.
Medical compound	S. E. Paddock	Delaware, O.
Suppository mold	P. I. Spenzer	Cleveland, O.
Truss	J. F. Groves	Whitefield, Co. Ga.

—Charles J. Gooch, *Patent Attorney.*

LOCK BOX 76, WASHINGTON, D. C.

FOR the week ending, September 2, New York city reported 11 deaths from typhoid fever, 1 from scarlet fever, 10 from measles, and 16 from diphtheria.

TO CONTRIBUTORS AND CORRSEPONDENTS.

ALL articles to be published under the head of original matter must be contributed to this journal alone, to insure their acceptance; each article must be accompanied by a note stating the conditions under which the author desires its insertion, and whether he wishes any reprints of the same.

Letters and communications, whether intended for publication or not, must contain the writer's name and address, not necessarily for publication, however. Letters asking for information will be answered privately or through the columns of the journal, according to their nature and the wish of the writers.

The secretaries of the various medical societies will confer a favor by sending us the dates of meetings, orders of exercises, and other matters of special interest connected therewith. Notifications, news, clippings, and marked newspaper items, relating to medical matters, personal, scientific, or public, will be thankfully received and published as space allows.

Address all communications to 1725 Arch Street.

INTERMENTS in Philadelphia, from August 30, to September 6, 1890:

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from August 24, 1890, to September 6, 1890.

APPOINTMENT.

BAXTER, JEDEDIAH H., Colonel and Chief Medical Purveyor, to be Surgeon-General, with the rank of Brigadier-General, August 16, 1890, *vice* Moore, retired from active service. Headquarters of the Army, A. G. O., Washington, September 1, 1890.

Leave of absence for one month, to take effect September 15, 1890, is granted First Lieutenant Theodore F. De Witt, Assistant-Surgeon. S. O. 76, Headquarters, Department of Texas, San Antonio, Texas, Sept. 1, 1890.

Changes in the Medical Corps of the U. S. Navy for the week ending September 6, 1890.

WISE, J. C., Surgeon. Detached from Torpedo Station, and to the U. S. S. "Alliance."

FITZSIMONS, PAUL, Surgeon. Ordered to the Torpedo Station, Newport, R. I.

BRIGHT, GEORGE A., Surgeon. Detached from the U. S. S. "Constellation," and to Naval Academy.

OLCOTT, F. W., Assistant-Surgeon. Promoted to be Passed Assistant-Surgeon.

WENTWORH, A. R., Passed Assistant-Surgeon, requests to withdraw resignation. Granted.

CRAWFORD, M. H., Passed Assistant-Surgeon. Detached from the U. S. S. "Monongahela," and granted two months' leave of absence.

KEENEY, JAMES F., Assistant-Surgeon. Detached from the U. S. S. "Richmond," and granted two months leave of absence.

LOWNDES, CHAS. H. T., Assistant-Surgeon. Detached from Naval Academy, and ordered to the U. S. S. "Richmond."

HOEHLING, A. A., Medical Inspector. In addition to present duties, ordered as President of Medical Examining Board at Philadelphia, convened by Department order, June 9, 1890.

KENNEDY, R. M., Assistant-Surgeon. In addition to present duty, ordered as member of the above Board.

OGDEN, F. N., Passed Assistant-Surgeon. In addition to present duty, ordered as member of the above Board.

MCCLURG, WALTER A., Surgeon. Granted a month's leave of absence from September 1.

KERSHNER, EDWARD, Surgeon. Granted two weeks' leave of absence from September 1.

The Times and Register.

Vol. XXI, No. 12. NEW YORK AND PHILADELPHIA, SEPTEMBER 20, 1890. Whole No. 628.

MEDICAL TEACHING ABROAD. ITS ADVANTAGES TO AMERICAN GRADUATES.

BY ERNEST LAPLACE, M.D.,
Professor of Pathology and Clinical Surgery in the Medico-Chirurgical College, Philadelphia.

NO one who has watched the rapid development of American medical education; the ample practical laboratory courses and hospital experience afforded the student eager after knowledge, will deny that the graduate of our best schools deserves the proud title which admits him to the ranks of the medical profession. That very consciousness of the gravity of the work he has undertaken, leavened with a true love of his profession, raises within him a desire to see and to learn, as far as his means will afford, all that can possibly bear upon his chosen profession before he embarks upon its practice; to see and meet the great masters, and gaze upon science at its fountain head, in another language, under other customs. It is then that knowledge gotten at the medical school is verily assimilated; then life and art become one.

He may see certain things done not as well as at home—his American heart then swells with just pride; but most probably his keen eye will not be long in observing the great thoroughness that pervades medical study and practice in Europe; the assiduity, patience and perseverance of investigators; the care, accuracy and deep learning of clinicians, and it then first dawns upon him that the great American *rush* through life, in medicine as well as in other avocations, must be tempered by that calm reflection, deep learning, and eager love of truth, which are the only foundations that will support the temple of medicine as erected by the Pasteurs, Kochs and Listers of the day.

Were this refining moral influence the only fruit of a post-graduate trip abroad, its value could not be overestimated, but from a more material and practical stand-point, no better step could be taken by a graduate, to perfect himself in general medical knowledge, or to adopt one of the specialties, than in devoting a reasonable length of time in the various European capitals, where the advantages for advanced medical teaching have been so systematized as to meet the requirements as well as the purse of almost any one. Let it be distinctly understood, therefore, that the graduate who goes abroad in search of medical knowledge must have either one of two objects in view. He desires to perfect himself generally on all the branches of medicine, or he wishes to devote his whole time and energy to the study of a special subject. This decision must be reached before leaving home, to make the most of the opportunities to be gotten in a limited time.

Generally speaking, Vienna is the center of post-graduate medical teaching abroad. The general hospital, with its thousands of beds, is the medical school as well; all the teaching by the professors and assistants being strictly clinical or practical laboratory work.

Connected with the hospital is the polyclinic, in which courses of six weeks' duration on the various special branches in medicine, are held from 8 A. M. to 8 P. M. A multitude of notices are to be seen on the board at the entrance of the hospital, from which a schedule may be formed by the student so as to occupy his whole time. Many courses are given on the same subject by different instructors, so as to benefit those who wish to devote themselves exclusively to a specialty.

Furthermore, the "Anglo-American Medical Society of Vienna," organized last year, is practically a club for the information and assistance of English-speaking students. This will be found of help for special information.

The brevity of these courses precludes that thoroughness which some students may seek; it is, therefore, recommended to devote a longer time under the private tutorship of one or more of the eminent specialists that abound in Vienna, both for clinical and laboratory work.

Berlin offers very nearly the same polyclinic advantages as Vienna, only each professor or docent is separated by a considerable distance from the other, and much valuable time is lost in the city travel; furthermore, the schedule does not admit of employing all the hours of the day, as in Vienna; one advantage is that, as a rule, the short courses are not as crowded as in Vienna. For special work of any kind, having a reasonable length of time to devote to it, Berlin is probably superior to any other city in Europe. Koch, Bergmann, Dubois-Reymond, Vir-

chow, Gerhardt, are names synonymous with all that is great in medicine. There is a wonderful gynecological clinic conducted by Olshausen, also one conducted by Martin. The pathological hygienic and physiological institutes are not surpassed anywhere.

Heidelberg, Greifswald, Göttingen also offer advantages for special study. Paris must also be visited. The Pasteur Institute presents an exceptional field for special work in biology. The great clinics of Verneuil, Péan, Tillaux, Potain, Dieulafoy require a careful visit. It has lately been announced that Paris will soon have a polyclinic established on the same system as that in Vienna. When this is realized, it will soon regain its former popularity as the place of study for American graduates. As it is, the eye clinics of De Wecker, Laudolt and Galezowski, and the laboratories of Cornil and Ranvier, are the chief attractions to the student. The Faculté de Medecine, granting no privileges to foreign graduates who desire to obtain a French diploma, but few Americans choose to spend the time and labor required to achieve that distinction. Considering the unlimited hospital facilities in Paris, we look anxiously to the near future when Americans will flock to the polyclinic of the gay capital as they do to-day to Vienna.

London has its attractions, but aside from exceptional cases, the American student finds himself satisfied with walking the various hospitals, and meeting the illustrious men of the day. Why this should be so to such an extent we are not prepared to say, except, perhaps, that the more foreign tone of continental life is more in accordance with one's idea of Europe.

It was not our purpose to give a full plan of medical study abroad, but simply to rouse those who can afford it to the necessity of a post-graduate course, seasoned with the refining and broadening effect of European travel. Each American graduate knows best what branches he wishes to study, and *how;* we hope we have convinced him of why he should go abroad, and, being there, told him *where* to direct his steps.

ARISTOL.

By WILLIAM F. WAUGH, M.D.

THE unpleasant odor of iodoform, and the failure of every means suggested to disguise it, has prompted a search for something which will replace this valuable agent. Naturally, the search has been mainly among compounds which, containing iodine, are nearly related to iodoform. Iodol has proved of some value, but a more promising combination is that of iodine and thymol, known as aristol, or dithymoldiodide. In this the proportion of iodine has been determined by Carius to be 45.8 per cent.

Aristol is insoluble in water or glycerin, slightly soluble in alcohol, and readily in ether. It is also quite soluble in oils; the solution being effected by rubbing; heat being avoided, which, as well as light, decompose aristol. It is non-irritant when dusted over the surface of an open wound or ulcer, and is not absorbed into the body, as the urine does not give the reaction of iodine while aristol is being used. I have noticed, however, that when applied to the ulcerated surface of a scirrhus, the starched clothes soiled by the discharge exhibited the characteristic blue coloration of iodine.

While aristol is as yet too recent an addition to our armamentarium to permit a positive conclusion as to its value, the trials already made are sufficient to indicate that we have in it an agent possessing remarkable properties. In my own practice I have the lolowing cases to report:

Endometritis.—A married lady, anemic and nervous, has had for months symptoms of corporeal endometritis; with tenderness of the uterus and left ovary, and soft, spongy, highly sensitive os uteri. Sexual intercourse has been impossible for months, on account of the great pain. Dysmenorrhœa, as a matter of course. A cotton wrapped applicator was dipped in glycerin and rolled in aristol powder; carried to the fundus uteri, and allowed to remain some minutes. Vaginal tampons prepared in the same manner were applied once daily; the intra-uterine applications being repeated twice a week. The next menstruation was painless; the tenderness steadily decreased with each treatment, and but little pain is now experienced upon intercourse. This is the result of less than one month's treatment.

Ulcerating carcinoma.—1Aady has had a mammary scirrhus removed several times, and at present the disease is beyond the reach of the knife; the tissues of the chest wall widely infiltrated and adherent, the cervical glands nodulated, and the central portions ulcerating. The débris was removed by poulticing, and aristol dusted thickly over the raw surface. Three days later the improvement in the aspect of the ulcer was so marked that we could hardly credit our eyes. After a week's treatment, granulations are springing up over the sore and it looks as if it were about to heal over. Should this improvement continue, I shall take means to introduce the aristol into the deeper tissues of the carcinoma, by hypodermic injection, and apply it over the surface by plaster or inunction.

Gleet.—A case of gleet of twenty years' standing. Several constrictions of the urethra exist; some of them very tight. There is also some impairment of sexual ability, emissions occurring before complete erection. The urethral mucous membrane is exceedingly sensitive; the passage of a bougie causing great pain, and being followed by an attack of urethritis so acute that I had some difficulty in convincing him that the bougie had not communicated a gonorrhœa to him.

Aristol was mixed with liquid and solid vaseline to make the consistency that of thick cream. This was introduced into the urethra in very small quantities. The pain and tenderness were at once relieved, the discharge ceased within a week; and to-day, the first time in twenty years, there is no sign remaining of the gleet. Whether there will be a corresponding improvement in the impotence it is too soon to say; but the patient believes that this is the case.

These are the only cases upon which I can report at present; but as aristol is now being tried in a variety of cases at my clinic, I shall make the result public at some future time.

Prof. Shoemaker has found aristol as efficient in psoriasis as chrysarobin, while the former does not stain the skin and give rise to conjunctivitis like the latter. In chronic leg ulcers, simple or specific, aristol is even more efficient than iodoform; relieving the pain and tenderness as quickly, and promoting cicatrization much more.

Dr. W. C. Wile states that in the general details of surgical practice he has found that aristol may be substituted for iodoform with advantage. So far as the limited experience of a few weeks goes, I can confirm this statement.

Eichhoff (*N. E. Med. Monthly*) gives the history of nine cases in which he employed aristol, with the following results:

1. *Varicose ulcer and parasitic eczema.*—Ten per cent. ointment of aristol in vaseline (the aristol first dissolved in olive oil) applied to the affected parts, and covered with gutta perchsa. Cured in one week.

2. *Lupus exulcerosus facieci.*—An old case, with great destruction of the soft tissues. Aristol was applied in the same strength as in the preceding case. Though a very large surface was covered with the ointment, there was no absorption, as shown by testing the urine for iodine. In four weeks the diseased surface was almost entirely healed. The combination of a germicidal action and the promotion of new tissue growth was beautifully exemplified in this case.

3. *Soft chancre.*—The aristol seemed to stay the progress of the disease, but proved inferior to iodoform.

4. *Psoriasis vulgaris.*—Ten per cent. aristol ointment applied. It proved a little slower than chrysarobin, but the disease was almost entirely well in ten days.

5–6. *Ringworm.*—Head shaved, washed with soap twice daily; five per cent. aristol ointment applied. Cured in ten days.

7. *Sluggish ulcers, following scabies.*—Five per cent. aristol ointment cured in five days.

8. *Seborrhoeic eczema.*—Previous treatment proved ineffectual, but a three per cent. aristol ointment cured in six days.

9. *Syphilitic ulcers, congenital.*—Sublimate dressing did but little good, and a ten per cent. aristol ointment was substituted. Healing went on rapidly, and in eight days the smaller ulcers had closed and the larger were almost well.

Brocq recently showed a case of epithelial cancer of long standing, in which the ulceration had almost entirely cicatrized under the use of aristol. The difficulty of securing such results in cancer indicates the importance of giving aristol a thorough trial in this disease.

Schuster makes a favorable report on the use of aristol in naso-pharyngeal syphilis. The drug was applied in fine powder, by a blower.

Schirren used aristol in ten cases of psoriasis, and confirms the reports already mentioned.

Lasser also confirms its value in psoriasis, but did not obtain benefit in lupus vulgaris.

Neisser gave aristol internally without producing the slightest effect. His results in psoriasis were less favorable than Eichhoff's; though he regards aristol as preferable to chrysarobin and pyrogallic acid. Gonococci were not affected by it. Several varieties of ulcers healed favorably under aristol. Eczema showed some improvement; while with lupus and soft chancre it had no effect.

Swiecicki,[1] of Posen, first published results obtained with aristol in gynecological practice. He reports twenty cases treated with aristol. In five the beneficial action was most marked. The cases were:

Endometritis. Uterus very slightly sensitive to pressure; secretion much diminished. Portio vaginalis normal. Tampons soaked in 10 per cent. solution in oil in the vagina, small rods containing fifteen grains of aristol, introduced into the uterus.

Endometritis, with erosions and hyperplasia of the cervix. Good result in seventeen days. As above.

Parametritis. The exudation much less, in four weeks can scarcely be felt. Introduction of aristol tampons as far as the portio vaginalis, inunction of 10 per cent. ointment over the abdomen, and aristol suppositories.

Fissure of the Cervix. Healing by first intention in eight days. The wound was dusted with aristol powder.

Eczema Vulvæ. Satisfactory. 10 per cent. ointment.

In none of the twenty cases was the slightest ill effect observed, and although somewhat large quantities of aristol were employed, no trace of toxic action was observed.

Hughes[1] has investigated the action of aristol in Seifert's Clinic for Diseases of the Nose and Throat, in Würzburg. He has found aristol of service in those conditions of the mucous membrane in which the secretion is much diminished in amount, or where it tends to undergo decomposition.

The first group comprises the cases usually described as rhinitis sicca, so often associated with pharyngitis and laryngitis sicca; aristol has here a most beneficial action on the secretion, and does not produce the slightest irritation.

The second group comprises those cases in which there is an atrophy of the mucous membrane, especially that covering the lower and middle turbinated bone, without decomposition of the secretion. In addition, Hughes reports several other states of the nose and larynx in which aristol has been found of service. The cases recorded are the following:

Rhino-pharyngitis sicca (nine cases). Secretion appeared again, not only in the nose, but also in the naso-pharynx. Insufflation of aristol powder.

Rhinitis atrophica (three cases). Free secretion from the nose, the mucous membrane moist and shining, the general condition much improved.

Chron. Conjunctivitis; dryness of the nose (one case). All previous treatment had been without result, the insufflation with aristol had a decidedly beneficial action.

Rhinitis atrophica: ozœna fœtida (six cases). Fœtor decidedly diminished, condition generally improved, the crusts came away easily.

Specific ozœna with perforation of the septum (two cases). Most beneficial action. Insufflation of powder.

Laryngitis sicca (two cases). The previously hoarse voice became quite clear after one brushing with silver nitrate, 1 per cent. solution, and insufflation of aristol for two days. The aristol did not produce the slightest irritation.

Laryngitis syphilitica. The insufflation was borne very well.

Aristol has a peculiar action in promoting the secretion of mucous surfaces. After operative interference in the nose, its use seems advisable, especially as a substitute for iodoform. Even when freely and frequently used, there need be no fear of toxic action.

Loewenstein[2] reports four cases of ozœna, three simple, one syphilitic, in which he has used aristol. In order to test the action of the drug, other adjuvant measures were not employed, simply douches of salt solution or water alone being used. The cases are:

Ozœna simplex (three cases). Fœtor disappeared in a few days, crust formation much less. Headaches disappear. Insufflation of powder.

Ozœna siphilitica (one case). Ulcers healed, formation of crust ceased, as also the bleeding, fœtor disappeared. Insufflation of powder 10 per cent. solution in collodion flexile painted over the ulcers.

In all the cases under the use of aristol alone, the formation of crusts and the fœtor ceased, in a time in which, by other means of treatment, it is rare to

[1] Wiener Klin. Wochenschrift, 1890, No. 18.
[2] Int. Klin. Rundschau, 1890, No. 20.

see any improvement. The easy application of the fine powder is also worth notice, while it covers the surface with an impermeable coat. The complete absence of any toxic action, and the power of destroying the fœtor, are also distinctly noteworthy.

Gaudin[1] reports favorably on the new remedy, which he distinctly prefers to iodoform, the general properties of which at least it has, if, indeed, it does not far exceed it; in its want of odor, harmlessness, unirritant action, and, above all, its marked power in bringing about the cicatrization of granulations. The cases reported by Gaudin are:

Psoriasis vulgaris (four cases). The patches soon disappeared, healing without any irritation. In one case in which the ordinary remedies failed to cure, aristol was used with good result. Ten per cent. solution in flexile collodion.

Varicose ulcers on the legs (two cases), in one also eczema. Iodoform and empl. hydrarg. biniodidi, which were used for purposes of comparison, had by no means such a rapid action as aristol. Aristol as powder.

Chancre on the lip and on the penis (two cases). Rapid healing; in three days the surface was dry and cicatrization had commenced. Aristol powder.

Eczema on a hairy surface (nape of neck and axilla). Itching ceased at once; after eight brushings the patient was discharged cured. Ten per cent. solution in ether.

Eczema on a hairy surface in a syphilitic patient. Cure after ten dressings. Ten per cent. solution in ether.

Dr. Soler y Buscalla[2] records the remarkable healing effect of aristol in venereal sores of various kinds and buboes. The pure powder was used in all cases, that the action of aristol *per se* might be observed. Special report is given of a syphilitic sore on the dorsum of the penis, and a phagadenic ulcer in which iodoform produced violent irritative symptoms; after a few dressing with aristol powder cicatrization commenced. The cases under treatment comprised hard chancre, simple ulcer, simple chancer on the penis, ulceration of the vulva, and several cases of suppurating bubo. In all cases healing occurred quickly, and aristol was repeatedly used with success in cases in which iodoform had failed. Dr. Soler y Buscalla describes, from the results of his own observations, aristol as a most valuable addition to our materia medica.

Rohrer reports his experience with aristol in the "Archiv. Internac. de Laringologia." He used aristol first of all in the acute and subacute suppurative affections of the middle ear, which occurred so frequently associated with influenza. After washing and drying the ear with cotton wool, aristol was insufflated over the external meatus and into the cavum tympani; a tampon of cotton wool was then introduced, to be removed by the patient every hour if the secretion was profuse; at the same time, in patients suffering from subacute or chronic rhinitis or pharyngitis, aristol was insufflated in the nose or pharynx respectively. The secretion rapidly diminished, the mucous membrane of the tympanic cavity became smooth, the swelling disappeared, and the perforations healed. The cases of otitis externa recovered very rapidly under treatment with aristol. The result was also very good in the cases of rhinitis, and different forms of ozœna, the treatment consisting in syringing with normal salt solution and insufflation of aristol powder. More than twenty cases were treated with aristol; in no single case was the least unpleasantness observed, or the slightest trace of toxic action. The action of aristol far surpasses that of the well-known remedies, more especially boracic acid, iodoform, and iodol. It is especially noteworthy that cases which only showed tardy signs of improvement under the use of the above-mentioned, were healed in a few days under aristol treatment.

Rosenthal[1] reported to the Dermatological Society of Berlin a case of lupus, the ulcerated surface of which was very beneficially influenced by the use of aristol (the drug had only been used a fortnight). Rosenthal showed to the same society another patient who had suffered for eighteen years from lupus erythematosus. Both cheeks were covered with seborrhoic crusts; the nose was implicated, and at the junction of the bony and cartilaginous portions there were two deep depressions in the skin. The ears were implicated like the nose, and the lobule had disappeared. The general butterfly-like form of the diseased surface was most marked.

The diseased surface was then cauterized with the Paquelin thermo-cautery, and at once dressed with aristol ointment, and the result has been most satisfactory.

Gaudin[2] read, on the 15th of May, 1890, before the Société de Médecine pratique de Paris, a paper in which he mentions, in addition to the ten cases already recorded, three others in which he has used aristol with very good results. These are, shortly:

Resection of elbow for malignant growth. Iodoform had produced irritative symptoms; under the use of aristol these disappeared, and the edges of the wound united without any suppuration.

Epithelioma of the uterus filling the vagina, and with a most fœtid odor. Iodoform could not be tolerated; cotton tampons dusted with aristol powder soon corrected the fœtid discharge, and portions of the growth were also detached.

Endometritis following abortion, sanious purulent discharge, uterus tense and bleeding on the slightest manipulation. After washing with warm water, bougies of ol. theobrom. with aristol were introduced: all the symptoms rapidly disappeared.

Guerra y Estape publishes in the "Revista de Enfermedades de la Infancia" his experience of the use of aristol in children's diseases. Although the odor alone is enough to deter us in the use of iodoform, we have in addition the toxic and irritative properties which produce, not unfrequently in adults and more frequently in the naturally weaker and less resistent persons of children, most unpleasant results. Moreover, the smell of iodoform is to many children unbearable, and at times even irritating. In private practice, too, a point of some importance is that the public—at least here—attach a very ominous significance to the smell of iodoform.

In all twenty cases were treated, and all with very good result. Three are recorded in more detail, viz.:

Extensive ulceration over the parotid gland in a lymphatic child of two and a half years. In seven days the ulcer had healed. The treatment consisted in daily washing with tepid water and dusting with aristol powder.

Chronic coryza, the nares blocked with crusts, in a scrofulous child of three years. The interior of the nose was cleansed with boiled water. Aristol powder was then insufflated. Healed in six days.

[1] Jour. de Derm. et Syph.
[2] Revista de Cienc. Méd. de Barcelona, No. 8, 1890.

[1] *Deut. Med. Zeitung*, No. 21, 1890.
[2] *Jour. de Méd. de Paris*, No. 23, 1890.

Ulceration on the thorax over the ribs, five cm. in diameter, edges livid and covered with pus; in a weak, lymphatic child. Washed with boiled water, and dusted with aristol powder twice daily; the suppuration ceased in twenty-four hours, and cicatrization soon commenced.

In order to test the action of the drug, he used only sterilized water as a cleansing agent, without the addition of any antiseptic. Aristol encourages the cicatrization of wounds and ulcers; ill bye-effects were not observed.

Eichhoff publishes in the *Deutsche Medicin. Wohenshrift*, on account of his further experience with the remedy, which completely confirms his previous provisional communication. Eichhoff has not limited his obserations to the cases described in his first paper, but has also used the drug in other diseases.

The result with favus, soft chancre, and acute gonorrhœa was negative; but it is worthy of note that patients suffering from the latter, in which 5 per cent. aristol oil was used as an injection seemingly without effect, recovered much more rapidly under other treatment than patients treated in a like manner in which aristol was not used. The other cases are as follows:

Mycosis tonsurans capillit, (eleven cases). Of these, nine were cured in from six to eight weeks under the use of 10 per cent. aristol ointment, none were epilated.

Sycosis parasitaria barbæ resp. montis veneris (eight cases). All the cases were cured in from two to four weeks under the use of 5 per cent. aristol ointment, or 5 per cent. solution of aristol in collodion flexile.

Eczema. Face, arm, scrotum, finger, forehead, (six cases). In five cases the cure was complete in from seven to fourteen days. On extensive surfaces 5 to 10 per cent. ointment was used, on smaller patches 10 per cent. solution in collodion flexile containing 10 per cent. ol. ricini.

Lupus (nine cases). Five Lupus maculosus, four lupus exulcerans. The surface in the former was caused to ulcerate by erasion with the sharp spoon or cauterization with Paquelin, in the whole nine cases cicatrization rapidly proceeded. In about two months after treatment, all the cases were seen, and in none had any relapse occurred.

Scrofuloderma (five cases). The flabby granulations were removed, and the whole five cases healed rapidly.

Gangrene of the skin following frost-bite: chronic ulcer of the leg. Cicatrized rapidly under the use of 10 per cent. aristol ointment.

Ulcerated gummata in tertiary syphilis. According to the sight of the ulcers, ointment, powder, or ethereal solution was employed. All the cases healed rapidly under this local treatment. Aristol surpasses all other remedies in the rapidity and completeness with which it produces cicatrization in tertiary syphilis.

Bubo, after soft chancre. Rapid healing with 5 per cent. ointment.

Gangrenous bubo. Granulation and rapid cicatrization under use of aristol powder.

Urethritis chronica (puellæ publ.) (nine cases). In six cases rapid recovery followed the use of bougies of ol. theobrom. with aristol.

Psoriasis vulgaris (two cases). Cured in fourteen days with ten per cent. ointment and 10 per cent. solution in collodion flexile respectively.

Eczema crustatum and moist condylomata round the anus were rapidly cured; a case of ozœma simplex lost its penetrating odor at once after a few insufflations of aristol powder.

A case of lupus erythematosus implicating the face, feet, and hands, and of years' duration, was rapidly cured by the drug. The surface was first destroyed, and the ulcers so produced treated with 10 per cent. aristol ointment. In ten days the patient was healed, with a clean, smooth, white cicatrix.

Pollack,[1] of Prague, has used aristol with advantage in place of other iodine compounds in hastening absorption. He has treated with it cases of epididymitis, parametritis, typhilitis, inflamed tubercular lymphatic glands in the neck, and enlarged thyroid.

Hypertrophy of thyroid. All treatment so far adopted had been without result. At first a soap mixture, containing 1 per cent. of aristol dissolved in a mixture of alcohol and ether, was used; later 10 per cent. ointment in vaseline. The enlargement was distinctly less in fourteen days, and the neck soon became quite normal in size.

Epididymitis (three cases). When the use of 10 per cent. aristol ointment was commenced the epididymus was more than twice as large as the healthy one. In four days there was a distinct improvement, and after ten days there was no trace of any enlargement, nor was there any pain.

Parametritis (three cases). There was a distinct improvement after using 5 per cent. ointment for two days, and in four days the tumor was scarcely to be felt.

Inflamed tubercular lymphatic glands (four cases). Five per cent. aristol in vaseline was used. There was a distinct diminution in the size of the glands. In all the other cases, and also in a case of typhlitis, the action of the drug was satisfactory; as also in a case of ulcus cruris and blenorrhoic ulceration of the nose.

I may here remark that while authors differ as to their estimate of the value of this remedy, there has been no report that has come to my notice in which the writer had not found the aristol of some benefit, and in some respects superior to the remedies previously employed. This can scarcely be said of any other newly introduced drug.

SULFONAL.

By W. DeLANO EASTLAKE, M.D.,
PHILADELPHIA, PA.
Member of the Japan Branch of the Royal Asiatic Society of England.

OF late years a large number of new drugs have found their way into the practice of medicine which, under the light of chemical research, have faded away into obscurity. Only a few have become firmly established and have fulfilled their requirements. The hypnotics have, perhaps, received the largest additions to their ranks; and a vast amount of experimenting upon sleepless sufferers has been carried on, to the edification of the physician, and at the expense of the patient's comfort. One by one these newer drugs, with their promising titles, have been abandoned, either on account of their inefficiency, or on account of the alarming accompanying or after-symptoms then produced. Among the few that have stood the severest tests sulfonal is foremost. Although the subject of numerous experiments, sulfonal must still be considered in its infancy; and, while personal experience is always the best teacher, a careful review of the results of the most important papers on sulfonal cannot fail to be of practical value to the busy practitioner, who neither has time to

[1] *Ther. Monatschefte*, 1890, No. 7.

devote himself to the study of any one drug, nor to read even a tithe of what is written about it.

Sulfonal was discovered by Prof. E. Baumann, of the Freiburg University, Germany. It is a whitish, crystalline substance, belonging to the disulfones, and has the formula

$$(CH_3)_2=C=(C_2H_2SO_2)_2,$$

and its complete name is diæthylsulfondimethylmethan. Sulfonal has neither odor nor taste; it is but very slightly soluble in cold water, more so in warm water, and easily soluble in alcohol, ether, etc.

Among the earliest researches with the drug are those of Prof. A. Kast, of Freiburg, who reported his results in an article in the *Berliner Klinische Wochenschrift*, 1888, No. 16. Kast's first experiments were made upon dogs, and it became evident that the drug exerted decided physiological effects upon the nerve centers and cerebral cortex, and was apparently harmless, even when administered in relatively large doses. Numerous experiments were also made with the drug upon healthy human subjects, and it was found that it neither acted as a narcotic nor intoxicant, and did not stupefy healthy persons who had no desire to sleep. If, however, the person was actually tired, and in cases where a desire for sleep existed which could not be satisfied, sulfonal increased the somnolency until sleep occurred. After these preliminary investigations, Kast proceeded to test the value of sulfonal by using it extensively upon the patients in Dr. Bäumler's wards in the University Hospital of Freiburg. It was given for sleeplessness from varied causes, such as febrile conditions, old age, insanity, nervousness, and organic diseases of the nervous or circulatory systems. The results were uniformly satisfactory. The dose required ranged from fifteen to forty-five grains, and sleep occurred within thirty minutes to two hours after the exhibition of the drug. The sleep thus produced would last from five to eight hours. Upon waking, the patients felt refreshed, and no disagreeable symptoms were noted. According to Kast's experiences with sulfonal, both in animals as well as human subjects, the drug has no unfavorable effect upon the heart or circulation, even when administered in full doses.

Several months later, Kast reported additional experiences with the drug in the *Therapeutische Monatshefte*. Various experiments showed that the best methods for the administration of sulfonal were as follows: The drug should be finely powdered, and then mixed with some solid food, or, better still, dissolved in a bowl of hot soup, a cup of tea, coffee, milk, or broth. This should be taken early in the evening—between 7 and 8 o'clock—or at supper. In this article Kast calls special attention to the value of the drug in the insomnia and delirium of typhoid fever.

Regarding the value of sulfonal as compared with other of the newer hypnotics, it seems that it gives better and more reliable results, when given in moderate doses, than amylene-hydrate or paraldehyde in maximum doses.[1] Chloral produces sleep more rapidly than sulfonal, but the sleep produced by the latter drug is more lasting. It has a decided advantage over the majority of hypnotics by being tasteless and odorless.

Kast's excellent results soon prompted other physicians and clinicians to try the drug, and in a little time the German medical journals were teeming with interesting and instructive articles on sulfonal. Countless cases were reported, the results of searching experiments recorded, and a vast amount of clinical experience presented. Any drug that has emerged from such a fierce battle with science and still holds its place among the foremost remedies in medicine, surely deserves not only careful consideration, but personal trial. True, sulfonal did not escape without a few scars. Several cases were reported in which the drug failed, and failed repeatedly, and others in which it was not well borne; but in the face of the overwhelming evidence in its favor, these cases have but little weight. Still, they should by no means be overlooked. In a case of phthisis reported by Dr. Carl Oestreicher in the *Berliner Klin. Wochenschrift*, a dose of forty five grains of sulfonal, while producing sleep, was followed by general weakness and malaise, which lasted the entire day. In another case, reported by the same observer, similar lassitude was observed on the day following the exhibition of the drug. Dr. Oestreicher's report includes one hundred and twenty-eight observations, and in all of these, with the above exceptions, the drug's action was entirely satisfactory, and all sequelæ absent.

One of the most careful reports of German investigators was that of Dr. Joseph Franz, which was published in the Transactions of the *Würzburger Physikalischen Gesellschaft*. Two hundred and sixty separate tests, upon eighty-two patients, were made. The first group comprised only cases of purely nervous sleeplessness. Sulfonal was administered eighty-two times. In seventy-eight instances excellent results were obtained. Only in one patient did the drug fail to produce sleep, and this was a phthisical subject accustomed to morphine. In two cases the hypnotic effect was delayed until the following morning. Franz found the drug useful in treating a case of morphine habit.

The second group of patients consisted of patients in whom the insomnia was caused by pain; in such the drug was used one hundred and seventy-eight times. In this class of cases sulfonal proved less reliable, although in only five cases was there complete failure in producing sleep. It was found, however, that in the majority of cases the intensity of the pain certainly did retard the hypnotic action of the drug, although not able to overcome it. The drug is, therefore, chiefly useful as a hypnotic and not as an anæsthetic or anodyne, as morphine or chloral. In the majority of cases Franz exhibited fifteen-grain doses, and found these all-sufficient.

In Italy, Dr. G. Algeri investigated the drug's action at the Asylum for Insane Criminals at Ambrogiana.[1] He used sulfonal in acute mania, imbecility, melancholia, dementia, epilepsy, acute epilepsy, etc., and almost without exception has found it to be prompt and certain in its action. True, the dose required to produce sleep varied greatly—in some cases as much as sixty grains being found necessary, while in others fifteen grains had the desired effect. Yet, even the largest doses produced no unpleasant accompanying or after-effects other than a slight drowsiness, which continued during the day following the drug's exhibition. While strongly recommending sulfonal in the treatment of insomnia in the insane, Algeri adds a word of caution in regard to the necessity of a careful selection of the proper doses in each individual case.

Coming to a review of the observation of American physicians, we find that those of Dr. Henry Wether-

[1] Dr. G. Rabas reported two hundred and twenty cases treated with sulfonal, in *Berl. Klin. Wochenschrift.*

[1] *Riforma Medica.*

ill, of the Pennsylvania Hospital for the Insane, which were reported in the *Medical and Surgical Reporter*, October 13, 1888, were among the first, and were also among the most complete. Briefly summarized, Dr. Wetherill used sulfonal two hundred and thirty times in eight individuals, with the following results:

An excellent effect, namely, continuous sleep, lasting from five and a half to nine hours, in one hundred and ninety-six instances, or 86 per cent.; a fairly good effect, namely, continuous sleep, lasting from four to five hours, in fifteen instances; an imperfect effect, namely, sleep lasting only two to three and a half hours in nine instances; and no hypnotic action in ten instances. The average dose employed was fifteen grains. In no instance was the administration of the drug followed by any unpleasant effects whatsoever, the sole physiological action being sleep, usually restful, refreshing, and prolonged. There was no appreciable effect upon either the pulse, temperature, respiration, skin, kidneys, or pupils.

At the same time, Dr. B. Sachs, of New York, investigated the drug's value,, and reported the results of his observations in the *Medical Record*, October 6, 1888. His results were not uniformly as satisfactory as those of Dr. Wetherill. He used the drug repeatedly in fifteen different patients. In two individuals the drug signally failed to produce any amelioration of the insomnia; in three cases six hours' sleep was procured; in two, five hours; in one case never more than three hours' sleep was secured, and this was followed during the next day by symptoms of dizziness and heavy-headedness. In the remainder of cases the drug afforded a good night's rest. The dose employed was thirty grains.

Sachs concluded that sulfonal is valuable in functional (neurasthenic) insomnia, and that it appears to justify the claim of its discoverer, namely, that it restores the natural desire for sleep. He found that it was easily tolerated by the stomach; that it did not produce headache unless given in doses of forty-five grains, or over; that it had no effect upon the circulation, and could be given in cases of fatty heart, and apparently in fever; in all of which respects it appeared to be superior to other hypnotics. From his experience, however, sulfonal appeared to have very slight or no narcotic virtues, and with some patients seemed to lose its effect if frequently administered.

The *American Journal of Insanity*, April, 1889, contained a careful report of eighteen cases in which sulfonal had been used. The writer, Dr. Wm. Mabon, of the State Lunatic Asylum, Utica, N. Y., used the drug in various forms of melancholia, dementia, mania—both acute and chronic, periodic insanity, and depression. Altogether, the drug was administered one hundred and nineteen times on one hundred and fourteen nights, as follows: In fifteen-grain doses, twenty six times; in thirty-grain doses, eighty-one times; in forty-five grain doses, nine times; and, finally, three times in sixty-grain doses. On eighty-three nights, sleep was produced which continued for six hours or more; on twenty nights, from three to six hours, and on eleven nights, less than three hours. The sleep thus produced was natural on ninety-seven nights, and restless and broken on seventeen. In two cases the drug failed to give satisfactory results. The time required to produce sleep was, on an average, one hour and a quarter. In one case a marked sedative action of the drug was manifest. The only unpleasant after-effect was a slight somnolence in two or three instances. In the class of cases observed, fifteen-grain doses seemed insufficient, but thirty-grain doses usually resulted in producing refreshing sleep. Sulfonal was found to be most efficient when administered in hot milk or gruel. In comparison with other hypnotics used in the same cases, it was evident that the sleep produced by sulfonal was calmer, longer, and more refreshing than that produced by any other hypnotic.

The innocuousness of sulfonal is ably demonstrated by the report of a case occurring in the practice of Dr. W. C. Wile. The case was reported to the Section of Diseases of Children, of the American Medical Association, at its last meeting, held at Nashville, in May, 1890, and was subsequently published in the *New England Medical Journal*, July, 1890. The case was that of a child, one and a half years old, who was given sixty grains of sulfonal by mistake. The infant slept continuously for twenty-four hours, the respiration and pulse being normal, and the temperature very slightly elevated. Upon awakening, it cried for food.

Dr. Wile has used sulfonal largely in the diseases of children, and has never observed ill effects arising from its employment. He recommends it most highly in the irritability, sleeplessness, and convulsions accompanying. "Given in the proper dose," he says, "and according to the age of the patient, it will quiet the irritability of teething; prevent, oftentimes, convulsions; aid in controlling the same; relieve the nervous excitement, and produce peaceful sleep." He has found that it does not constipate, leaves no sequelæ; does not depress the system, nor impair the appetite. In fact, it is accompanied by none of those unpleasant symptoms which are almost sure to accompany the use of opium, chloral, or the bromides.

One of the most able among the recent papers on sulfonal was that read before the American Medical Association, at its last meeting, by Dr. Henry M. Field, of Dartmouth College. From practical experience, he expresses the belief that sulfonal is the only pure and efficient soporific we now possess. According to his experience, age, or organic disease —which, when other hypnotics are used, must be carefully considered—need not be taken into consideration when sulfonal is employed, other than a careful selection of the size of the dose. Dr. Field has been unable to find any fatal case as resulting from the use of sulfonal. Idiosyncrasy is occasionally met with, and is the chief obstacle to the entire success of the drug. Dr. Field ventures the prediction that so many grains of sulfonal will buy so many hours' sleep. This, we think, is scarcely confirmed by the experiences of other clinicians. Dr. Field claims that so large a dose as fifteen grains is very rarely required in continuous administration. A patient who has taken such an initial dose for a night or two, and thus received a full impression, will subsequently require only twelve or ten grains, in order to obtain similar action. Again, Dr. Field has found that the drug may be continued for several weeks without any increase of the dose being necessary. Regarding the method of exhibition, Dr. Field favors that of simply dusting the powder on the tongue and washed down with water; or, it may be given in capsules if a small dose is employed.

It has not been the intention of the writer of this paper to indite an eulogy of this drug, but to present to the profession a truthful picture of its value, as set forth by clinical experience. Many papers, the tenor of which has made them appear to be the out-pourings of a blind admiration, have been excluded from

this review. Indeed, we have searched rather for adverse criticisms of the drug rather than complimentary.

To draw conclusions would, indeed, seem to be an almost superfluous task. The remarkable uniformity of the results obtained by clinicians, both here and abroad, and the almost unexceptional success obtained with the drug, speaks for itself.

Is sulfonal the ideal hypnotic? No! but surely its failures are few; and until we find that "Tree of Life, the leaves of which are for the healing of the Nations," we must not expect to discover panaceas, and must be content in seeing sulfonal permanently established as one of the most successful and reliable remedies in the field of therapeutics.

THE NECESSARY PEROXIDE OF HYDROGEN.[1]

By ROBERT T. MORRIS, M.D.,
OF NEW YORK.

STOP suppuration! That is the duty that is imposed upon us when we fail to prevent suppuration.

As the ferret hunts the rat, so does peroxide of hydrogen follow pus to its narrowest hiding place, and the pyogenic and other microörganisms are as dead as the rat that the ferret catches, when the peroxide is through with them. Peroxide of hydrogen H_2O_2 in the strong 15-volume solution is almost as harmless as water, and yet, according to the testimony of Gifford, it kills anthrax spores in a few minutes.

For preventing suppuration we have bichloride of mercury, hydronaphthol, carbolic acid, and many other antiseptics, but for stopping it abruptly and for sterilizing a suppurating wound we have only one antiseptic that is generally efficient, so far as I know, and that is the strong peroxide of hydrogen. Therefore I have qualified it, not as "good," not as "useful," but as "necessary."

In abscess of the brain, where we could not thoroughly wash the pus out of tortuous canals without injuring the tissues, the H_2O_2, injected at a superficial point, will follow the pus, and throw it out, too, in a foaming mixture. It is best to inject a small quantity, wait until foaming ceases, and repeat injections until the last one fails to bubble. Then we know that the pus cavity is chemically clean, as far as live microbes are concerned.

In appendicitis, we can open the abscess, inject peroxide of hydrogen, and so thoroughly sterilize the pus cavity that we need not fear infection of the general peritoneal cavity if we wish to separate intestinal adhesions and remove the appendix vermiformis. Many a patient, who is now dead, could have been saved if peroxide of hydrogen had been thus used when he had appendicitis.

The single means at our disposal allows us to open the most extensive psoas abscess without dread of septic infection following.

In some cases of purulent conjunctivitis we can build a little wall of wax about the eye, destroy all pus with peroxide of hydrogen and cut the suppuration short. Give the patient ether if the H_2O_2 causes too much smarting. It is only in the eye, in the nose and in the urethra that peroxide of hydrogen will need to be preceded by cocaine (or ether) for the purpose of quieting the smarting, for it is elsewhere as bland as water.

It is possible to open a large abscess of the breast, wash it out with H_2O_2, and have recovery ensue under one antiseptic dressing, without the formation of another drop of pus.

Where cellular tissues are breaking down, and in old sinuses, we are obliged to make repeated applications of the H_2O_2 for many days, and in such cases I usually follow it with balsam of Peru, for balsam of Peru, either in fluid form or used with sterilized oakum, is a most thorough encourager of granulation.

If we apply H_2O_2 on a probang to diphtheritic membranes at intervals of a few moments, they swell up like whipped cream and come away easily, leaving a clean surface. The fluid can be snuffed up into the nose, and will render a fetid ozæna odorless.

It is unnecessary for me to speak of further indications for its use, because wherever there is pus we should use peroxide of hydrogen. We are all familiar with the old law, "*Ubi pus, ibi evacua*," and I would change it to read, "*Ubi pus, ibi evacua, ibi hydrogenum peroxidum infunde.*" That is the rule. The exceptions which prove the rule are easily appreciated when we have them to deal with.

Peroxide of hydrogen is an unstable compound, and becomes weaker as oxygen is given off, but Marchand's 15-volume solution will retain active germicidal powers for many months, if kept tightly corked in a cold place. The price of this manufacturer's preparation is about 75 cents per lb., and it can be obtained from any large drug house in this country. When using the H_2O_2 it should not be allowed to come into contact with metals if we wish to preserve its strength, as oxygen is then given off too rapidly.

H_2O_2 must be used with caution about the hair if the color of the hair is a matter of importance to the patient, for this drug, under an alias, is the golden hair bleach of the *nymph's dispare*, and a dark-haired man with a canary-colored mustache is a stirring object.

PHENACETINE.

THOMSON[1] says: In any given case of nerve pain where one might suspect a weak or fatty heart, phenacetine is to be preferred to antifebrine. It does not seem to act quite so surely as the latter, but after using three and a half ounces of it, I much prefer it to antipyrine. Such is my experience of phenacetine, after a fair trial. In seven or eight grain doses every four hours, it is a safe and effectual remedy in all neuralgias, be they in the head, back, or any other part of the body.

Rifit (*Bull. de Ther.*) reports very favorable results from large doses of phenacetine in acute articular rheumatism, particularly that of gonorrhœal origin. He gives the fifteen grains every three hours the first day, increasing the dose the following day, until the pain is relieved and the joints become movable. This occurs as a rule when six to eight doses per diem are given. These large doses are continued for three days longer, then gradually reduced to three times per day fifteen grains one week longer, and then omitted. Treatment by this plan reduced the time to twenty-one days, while that by the salicylate is thirty-five, and by antipyrine twenty-five days. In twelve cases so treated no heart symptoms were noticed. Relapses are unusual if the above plan is followed.

RADEMAKER says that the hyperacidity of acute rheumatism is due to paralactic acid.

OUR STUDENTS' NUMBER.

IN the present number we present our readers with an epitome of the requirements of medical colleges in the country and abroad. The tables represent the work of months spent in corresponding with these institutions, collating and comparing the information thus obtained. For much of this we are indebted to the *Journal of the American Medical Association*, the Reports of the Illinois State Board of Health, and the Students' Numbers of the *British Medical Journal.* We trust that our efforts have been of some value, and that students and their preceptors will find these tables of use.

Lack of space inhibits an analysis of the text-books in common use; which was partially prepared for this number, but reluctantly omitted. The lecture system is responsible for a needless multiplication of text-books. Nearly all the college announcements give a list of works on every branch, that are each doubtless of value, but which the student is totally unable to peruse in the short three years of his college course. Were each chair to designate a single work, it is likely that a careful study of this would be of greater benefit to the student, than an attempt to choose between the conflicting views of a dozen.

And yet it is not an easy matter to choose the best. In Practice, for example, we have a number of excellent works, but not one that embraces the good points of all.

Flint gives very good descriptions of disease, but, in spite of Welch's work, his therapy is too nihilistic. People who do not believe in the efficacy of treatment are not apt to believe in the efficacy of physicians.

Bartholow errs on the other side. He cures too much; and when one finds that, in spite of his confident assertions, his remedies do not remedy, it is rather discouraging.

Roberts is the book for a beginner. He gives the definitions clearly; the book is well balanced; he avoids discussions, and sticks to well-established facts; but still his book is but a skeleton, and he gives facts rather than principles.

Loomis' Clinical Medicine is, we believe, the best of the American works on practice. He has the most recent work in many branches, and is well up to the times. He is not so clear as Roberts, nor so comprehensive, nor so dry.

Fagge's book is the best of modern works for the practitioner; it is a work of the highest order of merit; but it presupposes a degree of knowledge not generally found in the student.

Niemeyer's work is now becoming old; so that the practitioner must supplement it with more modern treatises. But in one respect it excels all others, and that is in the profundity of its reasoning. He was a wonderfully clear thinker, and the greatest of therapeutists in his day. If it be understood that the object of medical study is not so much the acquisition of facts as the training of the mind in correct methods of thought, then the superiority of this work is manifest. No human brain can acquire, by a sheer effort of memory, the facts of medical science. But Niemeyer not only gives the fact, but the reason for it; he shows why a thing is, because it cannot possibly be otherwise; and the student who fairly comprehends his reasoning, never forgets it. And though the latest editions of his work appeared before the brilliant discoveries of Koch and Pasteur had inaugurated the new era in medical science, the student will find scarcely anything to unlearn in Niemeyer. His work is a foundation broad enough to hold the modern structure. Great man! Profound in reasoning and vigorous in action. He has left behind him men of erudition, brilliant writers and accomplished physicians, but no successor worthy to wear his shoes. In studying his works, one can understand the love our fathers had for George B. Wood; and how Sydenham's works never grow old.

In the department of Physiology, we desire to call especial attention to Landois' and Stirling's work. It is really a manual of physiological therapeutics; and the physician who has practised long enough to know and respect the vital forces will find this book a veritable mine of riches. Get it, read it, and then thank us for calling your attention to it.

Much of our space in this number is taken up with reports on new remedies. So conflicting are the statements concerning these that the practitioner hardly knows what to believe. A digest of these, however, will often show the reasons for the discrepancy; in diverse methods of administration, or in the writers' ways of judging results. Miscellaneous experimentation often develops unexpected applications of the agents employed.

Among these new agents, one of the most promising is aristol. From present appearances it bids fair to replace iodoform in every thing except the treatment of chancroid. If subsequent experience confirms the early reports, it will become a prime favorite. In Philadelphia many surgeons have substituted it as a surgical dressing, and all the opinions given to us personally have been favorable.

Sulphonal is distinguished as a hypnotic by the certainty of its action, when the conditions are favor-

able. The most valuable article upon it that has yet appeared is that of Dr. Field, which is summarized in Dr. Eastlake's paper. It is a drug which should be prescribed with a clear idea of the indication, or failure will result. In fact, it may be said of nearly all the newly introduced chemical products, that they are sharply differentiated agents, intended to replace the old "vade mecum" of five drugs which were given for everything, by a whole shop-full of tools, each of which is to be used for one thing, and one only. This may represent in medicine such an advance as the separation into families was in anthropology.

We close with a few words concerning ourselves. Heretofore THE TIMES AND REGISTER has contained twenty-four pages of reading matter weekly, consisting of original articles, society proceedings, reports from the college and hospital clinics, editorials, correspondence, a digest of current medical literature, and another of current medical news. We have always felt that a weekly must be a news purveyor, and that original papers should not occupy as much space as in the monthly medical magazines. A weekly also offers the best medium for queries and replies, as the latter can be furnished so much more promptly than in a monthly. To give more space to these departments, and to further enhance the value of our journal, we have decided to add a series of monographs, each occupying sixteen pages. These are to be written upon practical subjects, such as most directly affect the practitioner. Of those already in preparation, we are authorized to announce the following: The Question of Abdominal Operation as it Affects the Family Physician, by Prof. E. E. Montgomery; The Management of Pulmonary Consumption, by Prof. Frank Woodbury; The Significance and Treatment of Convulsions, by Prof. Samuel Wolfe; Typhoid Fever, by Prof. W. F. Waugh. Other papers have been promised by Prof. J. N. Upshur, Dr. S. V. Clevenger, Prof. Lydston, and a number of other writers of eminence. Each paper is intended to be a complete review of the subject named, and the whole series will form a valuable collection of monographs, brought down to the date of publication. It is our present intention to publish one of these papers monthly; but if we receive the support from the profession we hope for, they will appear semi-monthly or weekly, thus making our regular issues of forty pages each. This can be done without increasing the present cost to the reader, if those who receive this number approve of our project and support it by their subscriptions.

WILLIAM F. WAUGH.

PHENACETINE.

IT is well, in the pursuance of knowledge, to occasionally stop and look backward, in order to form an idea of the advance obtained. In the field of therapeutics a glance over the past few years cannot fail but to afford satisfaction even to the most ambitious investigator. A series of remedies has been discovered, the value of which we are only beginning to realize. One which occupies an almost unique position, on account of its manifold properties, is phenacetine.

Phenacetine is a white, tasteless powder, insoluble in cold water, but soluble in glycerine; it may be given in powder, tablet, or pill form, and is usually exhibited in doses ranging from two to five grains. The drug was first taken up extensively during the recent epidemic of "*la grippe*," and in this disease it acted almost as a specific. It was found to be most valuable in controlling the muscular pains which attended the influenza; but indeed the experience of all who used the drug, and reported their results, shows that it controlled all but the catarrhal symptoms of the epidemic. In many cases, no other treatment was found necessary. Simultaneously with these observations, the drug's value in the treatment of whooping-cough was demonstrated. Dr. G. C. Irwin, in the *Archives of Pediatrics*, reporting a case of pertussis, in which severe spasms occurred hourly, states that phenacetine in half-grain doses, given every four hours, gave immediate and permanent relief.

Several other cases of a similar nature were reported by the *New York Medical Times*, and in other journals, also one case in which the cough attending an acute attack of pharyngitis was completely relieved by five grain doses of the drug. Many other articles have recently appeared in medical journals confirming the above experiences, and praising the drug both as an antipyretic and antineuralgic. It is not our intention, however, to rehearse in this editorial the history of past results; but rather to lay before our readers the present aspect of the drug, its uses, and the results obtained with it. For this purpose we have personally interviewed the resident physicians of the leading hospitals of Philadelphia, and carefully noted their experiences, examined temperature charts and histories of cases in which the drug has been and is being used, and questioned most carefully regarding negative results, etc.

In the Hospital of the University of Pennsylvania the drug has been used with unqualified success, both as an antipyretic and antineuralgic. Untoward effects have never been observed, and cases in which the drug has given negative results are almost unknown. Phenacetine has established for itself in this hospital the reputation of being the safest of all antipyretics, and at once the most efficient.

In the Jefferson College Hospital, the drug has not received such careful study. Dr. Hearn, the Medical Resident, has used it frequently as an antineuralgic, and has also observed a hypnotic action, which, however, is probably induced by the relief from pain. In certain cases the drug seemed to give negative results, but these were few. The anodyne properties of the drug were also manifest in the relief it afforded patients suffering from pain other than neuralgic, and its action was frequently remarkable, both for rapidity and efficiency. Dr. Dean, also a Resident in the Jefferson College Hospital, used the drug extensively in the female gynecological ward, and found it valuable in the treatment of the headache, so often accompanying uterine disease. Also the pains in the pelvic organs themselves were frequently completely relieved by the drug. In the maritime ward the drug did not give such good results, and frequently failed in the treatment of neuralgic headaches. In all cases never more than five grains were exhibited at a dose, and it should be mentioned that in the very same cases in which phenacetine failed, heroic doses of calomel or opiates had to be given when the action of these drugs was called for. The failure of the drug was, therefore, due rather to the insusceptibility of the patients to drugs, rather than to the

inefficiency of the drug itself. On the whole, however, his experiences were favorable.

The drug has received the most careful consideration, and the most admirable results have been obtained at the Pennsylvania Hospital, of Philadelphia. Phenacetine was practically first introduced into the wards of the Pennsylvania Hospital by Dr. F. B. Gummey, and it has now been universally used in the hospital for nearly two years.

The greatest value of phenacetine seemed to be in its marvelous antipyretic properties, and its chief use has been in the treatment of typhoid fever. The drug has never failed in a single instance to produce a rapid and considerable lowering of the temperature, unaccompanied either by cyanosis, heart symptoms, weakness, or any other unpleasant symptom. Doses of five grains were primarily exhibited, but the antipyretic property of such doses was found to be too powerful, the temperature frequently dropping from six to seven degrees, or from 105° to normal. Three-grain doses were, therefore, substituted, and found to be equally as efficacious, while not so powerful; the decrease of temperature ranging from two to three degrees. No depressing effects whatever have been observed to follow the use of the drug. It is always well tolerated by the stomach, and in no instance has it either caused nausea or vomiting.

The temperature having been reduced by phenacetine, usually remains low for ten or twelve hours. Phenacetine acted promptly where quinine and antipyrin entirely failed, and where sponging had to be abandoned on account of the alarming symptoms of cyanosis it produced. The delirium was also greatly relieved; the patients usually becoming quiet and rational soon after taking the drug.

In one case of unusually severe typhoid fever, three grains reduced the temperature from 105° to 103° and kept it there for twelve hours, and on the following day the administration of six grains of the drug reduced the temperature from 104⅘° to 98⅕° within a few hours. In this case phenacetine in three-grain doses was continually used throughout the entire course of the disease, and an ultimate recovery resulted. The long continued use of phenacetine does not appear to exert any accumulative effects whatever, and the same dose will be found equally as efficient after weeks of daily use, as when first administered.

Compared with other antipyretics, it undoubtedly takes the first place, the chief points which make it superior, being:

1. Its tastelessness.
2. The absence of gastric irritation following its use.
3. The absence of any depressing effect either upon the heart or circulation.
4. Its promptness.
5. Its power and the long continuance of its action.
6. The absence of accumulative effects.
7. Its harmlessness.

No case of poisoning from phenacetine is on record.

Dr. Gilman, Resident in charge of the Woman's Medical Ward of the Pennsylvania Hospital, also uses phenacetine continually in the treatment of typhoid fever, and with results equal to those obtained by Dr. Gumney, excepting that two and-a-half grain doses were generally employed, instead of three grains.

Regarding the anti-neuralgic properties of phenacetine, they have been found equal if not superior to those exerted by antipyrin. Excellent results were obtained by Dr. Gumney in three cases of acute rheumatism in which salicylic acid and the iodides had entirely failed; two-grain doses of phenacetine gave immediate and complete relief.

In a case of severe endocarditis, in which there were daily chills and alarming temperatures, five-grain doses of phenacetin repeatedly brought down the temperature from 105° to normal, and once a drop of ten degrees was noted. In only one instance was the antipyretic action of phenacetine absent, and this was in a fatal case of pyemia following a surgical operation.

At the Medico-Chirurgical Hospital, phenacetine has been used largely by Dr. Waugh as an antipyretic and anodyne. In neuralgias occurring in anemic persons, and in those suffering with organic affections of the heart, phenacetine is especially useful. He prefers small doses: two grains repeated every one, two, or three hours. In the dysmenorrhœa of anemic women it is an efficient remedy. Two cases of whooping-cough, both quite severe, were treated with phenacetine in half-grain doses every two hours. Both were well in less than ten days; the whooping ceasing in less than a week. In these cases the drug was given as soon as the whooping made the diagnosis certain.

Dr. Waugh has already recorded a curious instance of the use of phenacetine in measles. The drug dissipated every symptom and kept them away for about five days. It was then discontinued during a temporary absence of Dr. Waugh from the city, and meanwhile the disease recurred. Phenacetine was again given in small doses, and the affection passed over in a mild form, with far less suffering from catarrhal symptoms than is usual.

Insomnia is often the result of irritation, producing perhaps some rise in temperature, or, at any rate, the sensation of heat. The stimulation of coffee also causes sleeplessness. In these cases small doses of phenacetine act as a safe and efficient hypnotic, free from danger of every kind. So also when insomnia is due to pain of a minor degree, but yet sufficient to destroy rest, phenacetine will give relief. Perhaps not the least important of its hypnotic applications is in the case of children irritated by teething or indigestion; when one or two grains suffice to give mother and child their needed repose. In digestive troubles of infancy the drug undoubtedly acts as an antiferment; checking the processes of decomposition in the intestinal canal.

As has been stated, the above is a report of the drug's value as it is found at present in hospital practice, and no further comment is needed.

Our work ends here. The editor can only hold forth the light that has been kindled by careful research. It now remains for the profession to perceive and make use of it. And here we would urge upon our readers the value of the reports of individual experiences. The number of writers, or even occasional contributors, to medical journals is comparatively small, and scores of practitioners in every city in the Union fill their case-books with matters of the utmost practical importance only to have them stored away and forgotten. It is therefore the duty of every practitioner to add what he can to the evidence for or against a drug or treatment; and, if he can find a light amid the darkness of uncertainty and failure, let him set it on a bushel, that the whole house may be lighted.

A YOUNG lady is being treated in the Clifton Springs Sanitarium for an uncontrollable appetite for chocolate, which she has eaten so freely that her skin has assumed the tint of her favorite confection.

Tabular View of the Regulations of the Royal Colleges of Physicians and Surgeons, and of the Society of Apothecaries of London.

(Taken from the "British Medical Journal." Sept. 7, 1889.)

	Royal Colleges of Physicians and Surgeons.	Royal College of Physicians of London.	Royal College of Surgeons of England.		Society of Apothecaries of London.
	Double Qualification.	Licentiates.	Fellows.	Members.	Licentiates.
Age Required.	Twenty-one.	Twenty-one.	Twenty-five.	Twenty-one.	Twenty-one.
Evidence of General Education before Commencement of Professional Study.	Certificate of registration as a student by the General Medical Council.	Certificate of having passed examination in subjects of general education recognized by the General Medical Council, and of being registered as a student.	Certificate of registration by the General Medical Council.	Certificate of registration by the General Medical Council.	Certificate of registration as a medical student by the Medical Council.
Duration of Professional Study.	Forty-five months; at least three winters and two summers at a recognized school or schools.	Forty-five months; at least three winters and two summers at a recognized school or schools.	Six years; or members, two years in addition to the certificate for the diploma of member.	Four years, or not less than four winter and four summer sessions.	Forty-five months, dating from registration as a medical student, not less than three winter and two summer sessions at a recognized hospital and school of medicine.
Course of Lectures, etc., Required. Anatomy and Dissections.	Lectures, six months; dissections, twelve months.	A course of anatomy; dissections, twelve months.	Lectures during two winters; dissections, three winters.	Lectures, two winters; dissections, two winters.	Six months; practical anatomy and demonstrations, two winter sessions, or twelve months.
Physiology.	Lectures, six months; practical physiology, three months.	Physiology and practical physiology, each one course.	Lectures one winter, and practical physiology another session.	Lectures one winter; practical physiology another session.	Six months; histology with demonstrations, three months.
Chemistry	Instruction.	Instruction; time not specified.	One course.	One course.	Six months.
Pract'l Chemistry			Three months.	Three months.	Three months.
Materia Medica			One course.	One course.	Three months.
Pract'l Pharmacy			Three months.	Three months.	Three months.
Botany.	Not required.	Not required.	Not required.	Not required.	No certificate of attendance on lectures on botany is required.
Morbid Anatomy.	Three months; demonstrations in *post-mortem* room during clinical study.	One course; demonstrations in *post-mortem* room during clinical study.	Lectures, three months; demonstrations, three winter and two summer sessions.	Lectures, three months; demonstrations in *post-mortem* room.	Three months; *post-mortem* examinations during hospital practice.
Medicine.	Six months.	One course.	One course.	One course.	Six months.
Clinical Medicine.	Nine months.	Nine months.	One winter and one summer session.	One winter and one summer session.	Nine months.
Surgery.	Six months.	One course.	One winter session.	One winter session.	Six months.
Clinical Surgery.	Nine months.	Nine months.	Two winter and two summer sessions. Observation and examination of patients for three months.	Two winter and two summer sessions. Observation and examination of patients, three months.	Nine months.
Practical Surgery.	Required.	Required.	Six months.	Six months.	Three months.
Midwifery and Diseases of Women.	Three months; attendance on twenty labors.	One course, not less than twenty labors.	One course; not more than ten labors.	One course; not less than ten labors.	Three months; personally attended twenty cases of labor.
Clini'l Study of Diseases of Women.	Three months.	Three months.	Not stated.	Not stated.	Three months; besides this, a course of practical midwifery.
Forensic Medicine.	Three months.	One course.	One course.	One course.	Three months.
Hospital Practice.	Medical and surgical practice, three winter and two summer sessions.	Medical and surgical practice; three winter and two summer sessions.	Surgical practice, four winter and four summer sessions; medical practice, one winter and one summer.	Surgical practice, three winters and two summers; medical practice, one winter and one summer.	Medical and surgical practice, three winter and two summer sessions, with *post-mortem* examinations.
Hospital Appointments.	Medical clinical clerk, six months; surgical dresser, six months.	Clinical clerk, six months; dresser, six months.	House surgeon or dresser, six months.	Dresser, or (after a year of study) charge of patients under superintendence of a surgeon, six months.	Surgical dresser, three months; medical clinical clerk, three months.
Other Certificates.	Systematic practical instruction in medicine, surgery, and midwifery. Of having performed operations on the dead body. Instruction in vaccination.	Systematic practical instruction in medicine, surgery, and obstetric medicine. Instruction and proficiency in vaccination. Moral character.	Instruction and proficiency in vaccination. Comparative anatomy, one course. Operation on dead body.	Instruction and proficiency in vaccination. Examinations in elementary anatomy and physiology at medical school.	Birth; moral character; course of medical study; proficiency in vaccination, signed by a teacher recognized by the Local Government Board; operations performed on the dead body; attendance at class examinations. Signed by the Dean of the medical school.
No. of Examinations.	Three.	Three.	Two.	Two.	Four.
First Examination; When it May be Passed; Subjects.	After registration: (1) In chemistry and chemical physics; (2) materia medica and pharmacy; (3) elementary anatomy and physiology, at end of first six months at recognized school.	After registration as a student; chemistry and chemical physics; materia medica and pharmacy, and osteology.	After third winter session: (1) Anatomy and physiology; (2) after passing first and second examinations of Conjoint Board, or equivalent examination at University in Great Britain recognized for this purpose.	After second winter session; anatomy and physiology.	After registration as medical student; chemistry, physics, practical chemistry, materia medica, botany, pharmacy, prescriptions.

Tabular View of the Regulations of the Royal Colleges of Physicians and Surgeons, and of the Society of Apothecaries of London.– Continued.

	Royal Colleges of Physicians and Surgeons.	Royal College of Physicians of London.	Royal College of Surgeons of England.		Society of Apothecaries of London.
	Double Qualification.	Licentiates.	Fellows.	Members.	Licentiates.
Second Examination; At What Period it May be Passed; Subjects.	Six months after first examination. After eighteen months of study at a recognized medical shool, subsequent to registration; anatomy and physiology, which must be taken up together until the required standard is reached in one or other subject. Materia medica and pharmacy may be taken at this examination.	After eighteen months of study subsequent to registration as a medical student; anatomy and physiology.	After six years of professional study in surgery, including surgical anatomy and pathology, medicine, and midwifery. (Medicine and midwifery not required if passed for the membership, nor from candidates holding approved diplomas, degrees, or licenses, or from those intending to obtain a qualification in medicine and midwifery; the diploma of the college is not issued until proof of having passed the required examination is produced.)	After end of fourth year of professional education; in surgical anatomy, and principles and practice of surgery, medicine, and midwifery.	After twelve months' practical anatomy with demonstrations, anatomy (dissected subject), physiology, histology.
Third Examination; At What Period it May be Passed; Subjects.	Two years after second examination; forty-five months after registration. (1) Medicine; (2) surgery; (3) midwifery and diseases of women. (Forensic medicine and public health are included.) Each part may be taken separately, or all at one time.	Forty-five months after registration; two years after second examination. (1) In medical anatomy and pathology; principles and practice of medicine and therapeutics. (2) Surgical anatomy and pathology; principles and practice of surgery. (3) Midwifery and diseases of women. (Forensic medicine and public health are included.) Each part may be taken separately.			Forty-five months after registration. Principles and practice of surgery; surgical anatomy and operative manipulations; use of instruments and appliances; surgical pathology.
Fourth Examination; At What Period it May be Passed; Subjects.					Forty-five months after registration. Principles and practice of medicine, clinical medicine, pathology, morbid histology, forensic medicine, toxicology, hygiene, obstetric medicine, gynæcology, use of obstetric instruments.
Fees Payable.	At first or second examinations, £10 10s.; re-examination after rejection in either part of examination, £3 3s. At third examination, £15 15s.; re-examination after rejection in medicine or surgery, £5 5s.; in midwifery, £3 3s.	£5 5s. for admission to each examination. Candidates rejected at any examination must pay additional £3 3s. before readmission to examination. Total fee for license, £15 15s.	At first examination: members, £5 5s.; non-members, £10 10s.; £5 5s. returned if rejected. At second examination: members, £10 10s.; if not a member, £21. In latter case £10 10s. are returned in case of rejection.	Diploma of college, £21; £5 5s. at first examination; after failure at this examination candidate must pay an additional £3 3s. before being again admitted. At pass examination, £15 15s. paid, and £5 5s. retained on each failure.	For the four examinations, £10 10s.; re-examination after failure, £3 3s.
Rejected Candidates.	After first, second, and third examinations, readmitted after not less than three months. Candidates are re-examined in subjects in which they have been rejected.	After rejection at first or second examination, not again admitted until end of three months; after third examination, not till end of six months. Candidates are re-examined in subjects of rejection.	After rejection at first examination, candidates not again admitted for six months; after second examination, not till end of one year, unless Court of Examiners shall otherwise determine.	After rejection at primary examination, three or six months; after rejection at second examination, six months, unless the Court of Examiners shall otherwise determine.	Are readmitted after three or six months, as may be directed; and are re-examined in subjects in which they failed, except surgery, in which candidates are re-examined entirely.
Candidates (1) Exempted from Certain Portions of the Examinations; or (2) Admitted under Special Regulations.	(1) At first examination candidates who have passed a University examination for a degree in medicine in any subject of the first and second parts. (2) Holders of Colonial, Indian, or foreign qualifications entitling to practice, admitted to second and third examinations on production of evidence of age and of proficiency in vaccination.	(1) Candidates who have elsewhere passed examinations in the subjects of the first and second examinations; who have obtained a degree in surgery at a recognized university; who have passed an examination in surgery at a college of surgeons; who have obtained foreign qualifications entitling them to practice medicine or surgery.	(2) Members are admitted to first examination at any time after receiving diploma; to second examination at any subsequent time, if engaged not less than six years in study (or practice) of profession; in case of graduates in arts of a recognized university, five years.	(2) *a* Candidates who have studied in Scotland or in Ireland, or at recognized foreign or Colonial universities. *b* Members or licentiates of the other colleges of surgeons; and graduates in medicine or surgery of a recognized university, admitted to professional examinations on production of the necessary certificates and diplomas.	At first and second examinations, candidates who have passed equivalent examinations before any examining body recognized by the Medical Council.

PERNAMBUCO has had 4,000 cases of small-pox.

THE *Lancet* and the *British Medical Journal* of September 6, are students' numbers; and in them the reader can find fully detailed information concerning the medical schools and hospitals of the United Kingdom. The *Lancet* also contains some data concerning similar institutions on the Continent. Neither devotes any space to the American schools; but this lapse is amply filled by our present number.

CONSIDERABLE material has been prepared for this number in excess of the space at our disposal. This will be printed in next week's TIMES AND REGISTER. Included in this surplus matter is a digest of the State laws relating to medical practice, some talk about text-books, and the history of several very spicy interviews between Messrs. McCoy and Wildman and a member of our editorial staff. Copies of this supplementary number will be sent to any address on receipt of ten cents.

Tabular View of the Regulations of the Medical Examining Bodies in Scotland.

(Taken from the "British Medical Journal," Sept. 7, 1889.)

	Royal College of Surgeons of Edinburgh.	Colleges of Physicians and Surgeons, of Edinburgh, and Faculty of Physicians and Surgeons, of Glasgow.	Faculty of Physicians and Surgeons of Glasgow.		Universities of Scotland.
	Diploma.	Conjoint Examination.	License.	Fellowship.	Bachelor of Medicine and Master in Surgery.
Age Required.	Twenty-one.	Twenty-one.	Twenty-one.	Twenty-four.	Twenty-one.
Evidence of General Education before Commencement of Professional Study.	Having passed a satisfactory preliminary examination.	Having passed a preliminary examination, and being registered as a student by the Medical Council.	Having passed a preliminary examination and being registered as a student by the Medical Council.	Registration as a student by the General Medical Council.	Preliminary examinations by University, or Degree in Arts, or equivalent examinations.
Duration of Professional Study.	Forty-five months, including four winter sessions, or three winter and two summer sessions at a recognized school.	Forty-five months, subsequent to registration, including not less than four winter sessions at a recognized medical school.	Four years; including four winter sessions, or three winter and two summer sessions at a recognized school.	Six years; graduates in Arts or Science, five years.	Four years; one year being in the University, and another in the same or some other University.
Courses of Lectures, etc., Required:					
Anatomy.	Six months.	Six months.	Six months.	Two winter sessions.	One hundred lectures.
Practical Anatomy.	Twelve months.	Twelve months.	Twelve months.	Eighteen months.	Course of same duration.
Physiology.	Six months.	Six months.	Fifty lectures.	One winter.	One hundred lectures.
Pract'l Physiology.				Three months.	
Chemistry.	Six months.	Six months.	Six months.	One winter.	One hundred lectures.
Pract'l Chemistry.	Three months.	Three months.	Three months.	Three months.	Three months.
Materia Medica.	Three months.	Three months.	Three months.	Three months.	One hundred lectures.
Pract'l Pharmacy.	Three months.	Three months.	Three months.	Three months.	Three months.
Natural History (Zoology).	Recommended.	Strongly recommended.			Fifty lectures.
Botany.	Recommended.				Fifty lectures.
Pathology.	Or attendance in *post-mortem* room, three months.	Three months lectures; or attendance in *post-mortem* room of General Hospital.	Three months; lectures or attendance in *post-mortem* room.	Three months; and Practical Pathology three months.	One hundred lectures; or Pathological Anatomy three months, with supplementary course of Medicine or Clinical Medicine.
Medicine.	Six months.	Six months.	Six months.	Six months.	One hundred lectures.
Clinical Medicine.	Nine months.	Nine months.	Six months.	Twelve months.	Six months (one hundred lectures, Edin.), or two courses of three months.
Surgery.	Six months.	Six months.	Six months.	Six months.	One hundred lectures.
Clinical Surgery.	Nine months.	Nine months.	Nine months.	Twelve months.	Six months (one hundred lectures, Edin.), or two courses of three months.
Practical Surgery.				Three months.	
Midwifery and Diseases of Women and Children.	Three months; and not less than six cases of labor.	Three months; and not less than six cases of labor.	Three months; at least six cases of labor.	Three months; twenty cases of labor.	One hundred lectures; three months' Midwifery Hospital, and six cases of labor.
Med. Jurisprudence	Three months.	Three months.	Three months.	Three months.	Fifty lectures.
Hospital Practice and Hospital Appointments.	General Hospital, twenty-four months; Public Dispensary, six months; or Visiting Assistant, six months.	General Hospital, twenty-four months; Public Dispensary, six months; or three months dispensary, with three months' hospital clerkship; or six months pupilage with a registered practitioner.	Public Hospital, twenty-four months.	Twenty-four months.	General Hospital, two years; Out-practice of hospital, or of dispensary, or registered practitioner, six months.
Vaccination.		Six weeks.			
No. of Examinations.	One; final only. Candidate must have qualification in Medicine.	Three.	One; final only. Candidates must have qualification in Medicine.	Two; each examination may be divided.	In Edinburgh and Glasgow, four; in Aberdeen and St. Andrews, three.
First Examination, When it May be Passed; Subjects.		End of first complete year; Chemistry, Elementary Anatomy, and Histology.		Anatomy and Physiology (including Histology and Embryology); Chemistry (unless already passed).	
Second Examination; When it May be Passed; Subjects.		End of summer session of second complete year; Anatomy, Physiology, Materia Medica, and Pharmacy.		Candidates ten years qualified are exempted from this examination.	
Final Examination; When it May be Passed; Subjects.	After last winter session; Surgery (including Operative Surgery and Surgical Pathology), Clinical Surgery, and Surgical Anatomy.	End of full period of study: Medicine (including Therapeutics, Medical Anatomy, and Pathology), Clinical Medicine; Surgery (including Surgical Anatomy and Surgical Pathology), Clinical Surgery; Midwifery and Gynæcology; Medical Jurisprudence and Hygiene.	Surgery and Clinical Surgery, Clinical Medicine, Midwifery, and Medical Jurisprudence.	Pathology and Medicine (Systematic and Clinical) or Pathology and Surgery (Systematic, Operative, and Clinical).	

Tabular View of the Regulations of the Medical Examining Bodies in Scotland.—Continued.

	Royal College of Surgeons of Edinburgh.	Colleges of Physicians and Surgeons, of Edinburgh, and Faculty of Physicians and Surgeons, of Glasgow.	Faculty of Physicians and Surgeons of Glasgow.		Universities of Scotland.
	Diploma.	Conjoint Examination.	License.	Fellowship.	Bachelor of Medicine and Master in Surgery.
Fees Payable.	£15 15s.; in case of rejection, £4 4s. retained.	First and second examinations, each £5 5s.; additional, after rejection in all subjects, £3 3s.; after partial failure, £2 2s. Third examination, £15 15s.; after rejection, additional, £5 5s.	£15 15s.; in case of rejection, £4 4s. retained.	First examination, £8; second, £12; on admission, £5.	£22 in Edinburgh. £21; £5 5s. each of two examinations, £10 10s. at last examination of three; Glasgow, four fees of £5 5s.
Rejected Candidates.	Not readmitted under three months.	At either examination, not readmitted before three months; not re-examined in subjects in which an absolute pass has been obtained.	Not readmitted under six months.		Not readmitted until after another year of medical study, or such portions of a year as may be prescribed by the examiners (unless he has studied during another year two of the subjects).—*Edinburgh.*

PAPOID IN GASTRIC CATARRH.

WE will take it for granted that the proper regimen has been laid down for the patient; he has been told what and how much he is to eat, at what hours, with what beverages the food is to be diluted. He has been cautioned against the bad habits of eating and drinking that have originated the disease. The questions relating to alcohol, tobacco, exercise, and sleep, have been settled. What now remains for medicines? The therapeutic nihilist may say nothing. We say much. Catarrhs once firmly fixed in the mucous membranes have no tendency towards a cure, even when the exciting cause has been removed.

There are several drugs that have distinct remedial effects in this affection. We do not pretend to enumerate all, but simply those that have given the best results in our hands. Rhubarb and ipecacuanha, given in minute doses, have the property of stimulating the gastro-intestinal glands to secretion. The product is a normal secretion, and when the stomach is oppressed by the presence of unhealthy mucus, by the use of these drugs a healthy secretion may be gradually substituted. It is, however, of importance that the stomach should first be freed from the viscid mucus in it, that the medicine may reach the tissue it is designed to influence. The twentieth of a grain of ipecacuanha may easily be enveloped in a teacupful of mucus, so that the drug is entirely lost. For this reason we advise the use of hot water with alkalies, to be taken an hour before meals, the ipecacuanha following in about fifteen minutes. The effect of both is thus obtained before the ingestion of food begins.

If the secretion of mucus be profuse, the oxides of zinc and of silver are of value. They are astringent and alterative, and in relaxed states of the mucous membrane especially exert a powerful influence in restoring it to health. In one case where lavage alone had failed to relieve dilatation, the patient recovered practically under the use of one-quarter grain oxide of silver and two grains oxide of zinc, taken before each meal.

But there is another agent representing another and entirely different therapeutic principle that bids fair to prove of more value than all those hitherto mentioned. These are designed to prepare the stomach, or to directly and antagonistically attack the disease. The principle we now refer to is that of *coaxing* the organ back to its duty. He is the best physician who can restore health to a diseased function, or organ, with the least disturbance of the body, and following most closely the processes of nature. The use of ipecac approaches this; but there is another and better way of getting at the difficulty. It has been noticed by every physician who has used pepsin, that the amount of increased digestion is out of all proportion to the direct action of the quantity of pepsin given. This is due to the fact that when digestion is once started by artificial means the stomach will continue the process, which it was not however able to set in operation independently. We speak now from observations made clinically, and not from physiological experiment. It is obvious that a continuation of this action tends to re-establish the regular performance of natural digestion; in fact, it is, as we have fancifully termed it, coaxing the stomach back to its duty.

Pepsin, active in an acid medium, is obviously not the drug to be used here, as the digestion carried on in the stomach during the important first quarter or half hour, is alkaline. Here the saliva completes the action began in the mouth, and continued in the stomach, until stopped by the flow of the acid gastric juice. Until that occurs, pepsin is inactive; or it may be rendered permanently inert by the action of the alkali. Pepsin, then, is not a certainly efficient agent when given before meals.

We have here, then, a clearly-defined need for a remedy, and fortunately we have that indication accurately fulfilled by *Papoid*. For in this substance we have a powerful digestant which will begin the work of peptonizing albumen in an alkaline medium. It does not interfere with the action of saliva in converting starch into grape sugar, nor does saliva interfere with papoid. The formation of peptone is commenced, and when the natural stimulus of food has caused the secretion of the gastric juice, the pepsin simply continues the process until completed. Nor is there any abrupt transition from papoid-alkaline to pepsin acid peptonization, for, according to Clayton, papoid continues its action even after the secretion of acid has commenced.

If the secretion of abnormal mucus in the stomach is excessive, it is well to give the hot, alkaline water half an hour before meals, and the papoid immediately before eating. But in most cases this is unnecessary, as the papoid itself quickly rids the stomach of mucus. It may then be given in the form of tablet; say in the dose of two to five grains, with a grain of potash or soda, and a minute amount of ipecacuanha or rhubarb. Papoid is harmless to the healthy stomach, and, being of vegetable origin, is free from organic ptomaines. In acid dyspepsias it may be given with larger doses of potash; or, it may

be given in combination with diastase. Maltine and papoid form an excellent combination. Whether the asserted virtues of papoid, in dysenteric and diarrhœal diseases and in intestinal parasites, depend solely on its digestive powers or not, I am unable to decide from personal experience.

There is another use of papoid that, though not strictly physiological, will still be of value as long as human nature continues as degenerate as at present; for it is lamentably true that man still hankers after the flesh-pots, and, though he has more red corpuscles in his blood than are at all good for him, he will imperil his prospects of longevity by eating big suppers of rich, nitrogenous viands, instead of restraining himself to the fruit and parched peas which a correct appreciation of his physiology indicates as the proper diet. Such men *will* disregard our warnings and attend lodge suppers, wine parties, etc., where all sorts of rich food are taken. Now, papoid appears especially powerful as a digestant of just such food; croquettes, salads, game, are powerfully acted upon by this agent. Especially is this the case with that intractable delicacy, lobster. Men who like lobster like it very much indeed; but we often see them looking with longing eyes upon this, to them, forbidden fruit. Papoid digests lobster in any form with remarkable rapidity. Even when lobster and milk have been taken together, and the result is a hard, compact mass of casein, papoid will disintegrate it in a very short time. To these good livers, therefore, we can allow an indulgence in their favorite food, if they slip a few tablets of papoid into the vest pocket before setting out for the "lodge." It must not be forgotten that the effects of too great a digestion of food are more dangerous than the attacks of indigestion, unless the patient will diet himself properly before and after his feast.

Book Notices.

A Dictionary of Practical Medicine. By Various Writers. Edited by James Kingston Fowler, M.A., M.D. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1890. Royal octavo, pp. 942, half morocco.

In this work Dr. Fowler has presented in a concise form an epitome of subjects comprised under the head of Practical Medicine and Gynecology. The arrangement resembles that of Quain, but is more condensed. Each article treats of the subject under the heads of Symptoms, Course, Diagnosis, Prognosis, Pathology, Morbid Anatomy, Etiology, and Treatment. From the very limited investigation we have been able to make (the book is fresh from the press), Dr. Fowler's work seems to be exceptionally well done; the matter is fully up to date, and the book is a valuable one for ready reference. The practitioner who has no time to "wade" through acres of print in search of practical information will find this book just what he wants.

A Manual of the Practice of Medicine. By Frederick Taylor, M.D., F.R.C.P. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1890. Cloth, 8vo, pp. 895 Price, $4.00.

A concise account of the present state of medical practice, giving special attention to Symptoms, Diagnosis, Prognosis, and Treatment. Plenty of facts and not much theory. The book is a good one for students in their first course; to be followed by the more extensive works.

Wood's Medical and Surgical Monographs. Vol. 7. No. 2. 243 pages. Price, $1.00, or $10.00 per annum.

The present number of this valuable series contains the following papers: Morbid Blushing, its Pathology and Treatment, by Harry Campbell, M.D.; Alcoholism in Women, by Dr. Thomeuf; The Different Methods of Lifting and Carrying the Sick and Injured, by G. H. Darwin, M.D.; Treatment of Ingrowing Toe-Nail, by Joseph Amiard, M.D.; Chronic Bronchitis and its Treatment, by William Murrell, M.D.

Physicians' Leisure Library. No. 6. Containing Intestinal Diseases of Children. By A. Jacobi, M.D. Two volumes together. Pp. 266. Cloth, 50c.; paper 25c. each.

Dr. Jacobi is an authority on children's diseases, and his subject is one of the most important in the range of practical medicine. The reader will be amply repaid for his trouble in sending for this book.

A System of Oral Surgery. Being a Treatise on the Diseases and Surgery of the Mouth, Jaws, Face, Teeth, and Associate Parts. By James E. Garretson, A.M., M.D., D.D.S., etc. Illustrated with numerous wood-cuts and steel plates. Fifth Edition. Thoroughly revised, with additions. Philadelphia, J. B. Lippincott Co., 1890.

Oral surgery includes dentistry in a similar sense as it in turn is included by general surgery. The author says, in his preface, that dentistry, when practised disassociated from medical knowledge, is found to be of very little service to a community, and this suggestion is found so amply and irrefutably exhibited and demonstrated on his pages that no one will fail to give it his assent. A thought in connection with this is the pecuniary use to be made of the book here considered, by a great host of poorly paid and but partially employed country practitioners. The volume contains, as part of its contents, the full subject of practical dentistry, everything being told in such simple language and so exhaustively illustrated that, considering the incomes of the modern dentists, it would seem that here is the veritable bonanza of which so many poor physicians are in sore need. Dr. Garretson, being himself a surgeon, writes of his subjects as a surgeon would be expected to write. Every matter is presented from the stand-point of general principles, consequently is free from involvement and obscurity. If any money-worried practitioner desires to turn shekels, after a legitimate manner, in the direction of his needy pockets, we suggest that he think, not only twice, but many times, before turning from the possibilities contained in what is here offered him.

Still another thought in connection with this work is an estimate of the good judgment, and as well the practical use made of the nation's money, exhibited in the purchase of an edition, by a late surgeon-general of the army, and its distribution to all the army posts. An army surgeon knows exactly how to use such knowledge as is afforded in a book like this, needing alone the hints and illustrations it offers in order to put them to an immediate practical use, while question, as to the need for such practice among soldiers, is not so much as open to consideration. This use of the volume by army surgeons seconds our suggestion as to its utilization by the country physician. While this work is the chief text-book of the Philadelphia Dental College and Oral Hospital, yet its meaning includes the professions of dentistry and medicine at large. It constitutes one of the series of the medical text-books of the Lippincott house.

THE WEST INDIES AS A SANITARIUM.

By WILLIAM F. HUTCHINSON, M.D.

SUNNY climes, equal temperature of torrid heat, beautiful scenery, and all magic of change, cannot always prolong life.

It is especially important, in choosing a locality for a sick man for whom change is deemed advisable, to consider carefully what effect certain climates have upon certain classes of disease, and to learn as accurately as may be, the environment to which he will be subjected when once there.

I use the word subjected because I mean it. It is a serious matter for any one who is unaccustomed to travel, indeed to almost every one, to pull up stakes that have been driven deep and long, and start; so serious that most who go must stay for a time, if they like it or not.

In a previous chapter I have spoken of a few diseases that are benefited by winter change to tropical climate with temporary residence therein, and now propose to allude to others that should not be sent thither, as experience shows that they are unlikely to be improved by the trip.

Alluding to what I have there said, I may, perhaps, be pardoned for repeating a statement that a careful selection of climate is absolutely essential to climate cure.

More than once, in fact more times than I can now remember, I have seen sick people banished from home, friends, and the delights of their own fireside, without the smallest chance of permanent improvement following the change, either for the purpose of relieving some tired doctor of an incurable patient, or to gratify the wishes of the patient himself.

It is indeed a pitiful sight when one of these poor fellows steps ashore at Nassau or Barbados, with every sign of incurable consumption in his emaciated form and lustreless eyes, and to think that the only possible way in which he may see his native land again is by vision from the next world.

The other day I stopped such a man as this in the street at St. Kitts. "Where do you come from," asked I. "From Philadelphia," he answered. "Yes? Do you come out here for your health?" (an unnecessary question, by the way). "Yes, by the advice of my doctor," (naming a well known specialist of that city). "Had your doctor ever been in the West Indies, do you know?" "I don't think he had, sir, because when we were talking about the islands, and I wanted to know which one would be best for my peculiar condition, he answered, 'It does not make any difference, they are all just alike, go to which one you choose and make yourself comfortable.' So here I am, and so far as I can see, without much chance of either making myself or being made comfortable, in this island, at least."

"Do you know, sir," he continued, "if any of the other islands are better than this for a man whose lungs are half gone?"

"Why, yes," I replied, "this is probably the worst of all, for here there are neither hotels nor any means of passing away time excepting praying to the good Lord to let you live long enough to get back home again. You should have gone to Barbados, where the air is much dryer than here; where there is a choice of three or four hotels, and where there is plenty to occupy your time, even if you should want a change of occupation every day."

"Well," he said, "that's all these doctors know about things. If mine had told me what you tell me now, I might have been comfortably settled in Barbados by this time, instead of looking around St. Kitts for something to eat."

"How long have you been here?" I asked.

"A week to day."

"Are you feeling better, and does the air agree with you? Do you cough less, and is your appetite

better?" were some of the questions I asked this poor fellow, in the interests of the sick men to come after.

"I think," was the reply, "that I do cough less; but then the weather at home, when I left, was simply awful, and the perfection here of the temperature is such a change that one must be well-nigh dead not to gain by it; but I find that the constant perspiration brought on by the temperature, even without the smallest exertion, and which continues night and day, is making me sensibly weaker, and I fear that I have not done right in coming away from home at all."

I could not find it in my heart to tell the poor fellow that I thoroughly agreed with him. I have not heard since what became of him, but have no hesitation in saying that it was a serious mistake to send a case of consumption in any form or at any stage, except perhaps the very first of bronchial irritation, to these islands of the south; one reason being that the temperature, an absolutely permanent one for certain seasons of the year, is always sufficiently high to produce perspiration, which in a well person, or one affected by certain renal diseases, is a good thing, but which in a consumptive weakens the patient.

The warm, soft air, laden with moisture from surrounding sea, softens down diseases of lung tissue with astonishing rapidity. Cavities form to a rapid extent there, broaden swiftly, and destruction of these organs proceeds at a pace redoubled by the climate.

In all my twenty years' experience among the tropics, I have never seen a case of tubercular disease improved to any extent or in any permanent way by a residence therein, temporary or otherwise. On the contrary, it has been my sad lot to aid in preparing for the grave more than one lonely friend who had left all that life holds dear behind, in order that he might seek a futile chance for life; and I cannot say in too strong words, nor with too emphatic accents, that it is worse than useless to send consumptives to these islands. It is murderous.

I do not, in this statement, include such diseases of the throat as are catarrhal, irritative, or depend for continuance upon malignant northern winters. On the contrary, all these forms are rapidly improved, and in many cases permanently cured by the change.

Loss of voice, especially dependent upon catarrhal inflammation of the larynx or chords, disappears like magic. Rough accents soften down beneath the influence of the warm salt air and continuous moisture, and the change seems incredible to the sufferer.

Pains that go shooting about the chest, increased by deep inspirations into acute agony, and neuralgia, dependent upon pleuritic adhesions, also disappear after a short time.

Forms of cough that are dependent upon throat irritation, whether the same be nervous or follicular, do not last in this climate more than twenty-four hours; in fact, they are gone so quickly that it is a matter of wonder with the patient when they disappear, and he asks himself if he was not mistaken in supposing he had any.

It is, therefore, my deliberate opinion that of the two classes of diseases called consumption in the north, one being true tuberculosis and the other functional disease, or nervous throat disease, the first has no business in any tropical climate, but should be sent inland to some place like Colorado. The second does well here if sufficient time be given to consummate the cure that a flying trip only gives an opportunity to have commenced.

Tropical islands are very bad places for rheumatism; the same constant moisture that plays so large a part in curing nervous difficulties produces and intensifies all forms of rheumatic inflammations. It is a common disease. I cannot state the exact percentage, but from the number of natives that I have seen complaining of it, I am satisfied that it is a staple malady.

Probably a larger percentage of these cases than with us, are muscular, for the reason that there are no sharp changes of temperature to intensify a passing irritation into acute inflammation; but they are sufficiently annoying. Three times have I been prostrate with lumbago which was difficult to be rid of, and in each case it followed a seemingly trifling cause.

The skin is constantly in a state of high activity; at no time, night or day, is it dry, and the result of even a slight breeze striking this wet body is to lower its temperature a little. It is but a trifle, probably not felt at all, or, if felt, but eagerly welcomed as a pleasant relief from previous heat.

You do not even draw the loose wrap over your evening dress, or take the trouble to cover bare shoulders with more than a lace veil, but when next morning comes, there is an acute attack of lumbago to face. You are tied to your bed as if every muscle when put in motion was a red-hot bundle of wires. Nothing but absolute quiet can prevent acute agony, and this is as hard to cure in the tropics as it is here, even for doctors as hard to bear. It can, however, be totally avoided, as I have learned by experience during the last three years, by wearing pure woolen underclothing of medium weight next the skin, and changing it as often as it gets wet with perspiration. The latter is as important a precaution as the former, for wet flannel is not in any degree an improvement over dry cotton.

So far as cases of acute or articular rheumatism are concerned, they do not do well when brought here, and I advise the selection of a different climate for them.

Diseases of the eyes are not uncommon in these islands, which are as a rule composed partly of coral, some of them entirely so; and the intense whiteness of streets, buildings and beaches, in full glare of vertical sun, is bad treatment for those that come from abroad.

It is necessary to protect these sensitive organs everywhere in the tropics, by shading them from the sun with umbrellas whose lining is green, and by constantly wearing blue or smoked goggles. Neglect to follow this advice will be almost sure to be followed by some form of temporary blindness. If anything of this kind should occur, a mild astringent eye lotion with seclusion from the sun for a day or two, will be curative. If there is any tendency in a patient to inflammatory conditions of the eye, he must be thoroughly impressed with the necessity of great additional care when he goes to the islands.

Although zymotic diseases are not common in the islands, they still exist, modified in a large degree by the almost perfect drainage that exists everywhere, by a profusion of pure water, a comparative disuse of meat as a diet, and constant life in the open air. Nevertheless, those that are contagious may be communicated, so that a malignant case may develop in a stranger from a mild one in a native.

I recall as sad a case of this nature as anything that has come within my ken for many a year, that happened during the past winter at the island called St. Eustatius. A retired sea captain, who had been living for some years in the city of New Bedford, and whose children had died, to the number of five, from chest diseases dependent upon the malignant climate of New England, persuaded his wife to take the three

remaining ones and escape the wrath that he feared was to come when the cold winter of 1889 began.

They came to these beautiful islands where there was every promise of continuous health. A short time after their arrival, the captain noticed that several of the children, with whom his own were in the habit of playing daily, had sore throats. He was sufficiently on the alert to make inquiries as to the nature of this sore throat, but could find no history of anything serious. A few days passed of comfort and happiness, and the parents congratulated themselves upon their wisdom on making the change.

One bright morning their little boy awoke with a high fever and considerable pain in the throat. The mother was alarmed at once, and sent for the medical man, who reassured her by saying that it was probably a similar case to those around, none of which had proved fatal.

The next day the child grew rapidly worse, and the little girl was attacked in the same way.

The parents' alarm redoubled, and the medical man still assured them there was no cause to worry.

The next day the third child was attacked, and this was too much for the mother to stand. A bed was procured, and the family moved across to St. Kitts, a couple of hours sail across a quiet sea.

Once there, the surgeon-in-chief, Dr. Branch, promptly pronounced the case malignant diphtheria, and within three days more two of the children were dead, and the third in a fair way to recover.

I do not think in all my wandering I have ever listened to a more pitiful story than this told me by the bronzed old captain, amidst fast flowing tears from his grieving wife.

Disease of the digestive organs are only common here amongst strangers, who persist in bringing to the islands northern appetites, and in demanding that they be supplied by northern food. They eat as much food in Martinique as they do in New York, and sit at the table of the hotel wondering at the quantity of fruit and vegetables devoured by those to the manner born.

It must be remembered that the tropics furnish sufficient to satify the body, when the inner fires are fed with fuel that burns slowly, and abstain from loading the system with anything requiring much effort to get rid of. One is not often comfortable until the blood is thinned down from its sluggish northern flow, and only then begins to feel well when to the thinness is added a perceptible acidity.

It is my habit, as soon as I arrive in the tropics, to begin eating fruit in great profusion, both at the early morning meal and through the hours of the forenoon, abstaining entirely from meat. When I have taken so much as to produce a continuous acid taste in the mouth, and a feeling as if the teeth were on edge every time an acid touches them, I restrict myself to two oranges and a tumbler of cocoa-nut milk in the early morning, eating meat with great care, living chiefly on vegetables and fish. In this way I avoid altogether all dyspeptic derangements, and am able in a few days to stand the heat and prolonged exertion as well as the natives.

I think strangers would do well to follow my example in this respect, at least to some extent.

Should indigestion or dyspepsia follow the injudicious use of meat, it is much better to apply to one of the thorough qualified native physicians than to take drugs from the pocket-case that invariably accompanies travelers.

One of the ladies of my party carried two medicine cases, either of which contained a greater variety and better selection of drugs than the ship's chest, and when we returned, both were in a state of depletion.

In almost every one of the islands there are native remedies unknown in the United States, that are much better fitted for those localities than imported ones, and it is therefore better to have a native doctor.

GUADALOUPE, W. I., March, 1890.

REVIEW OF PROGRESS IN MEDICAL AND SURGICAL ELECTRICITY.

By WILLIAM R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

HIGH-TENSION FARADIC CURRENT IN GYNECOLOGY.—Böse employs this form of current extensively in pain associated with oöpharitis. His direction is to place the anode in the vagina, and the cathode over the abdomen by a large plate. He also says his electrode is bi-polar. He also uses it in pain due to exudates, which is relieved thus; but no effect toward absorption in such cases is found, nor in subinvolution. Although instances are rare of resolution of pelvic exudates, yet occasionally I have had complete disappearance occur under Faradism alone—galvanism being, of course, the main reliance where it is used strictly by the physician. Two other errors may be noted: First, there is no anode or cathode in faradic poles, the current being alternating. Second, large abdominal plates in ovarian disorders are useless; the current must be accurately localized over the ovary by either electrode. Again, bi-polar electrodes are unfitted for such work; but he may mean a *divided* electrode, one to each ovary simultaneously.

Munde in a recent paper urges galvano-puncture in lieu of the Apostoli method in fibroid, instancing four cases thus cured, whilst in eight no cure resulted from the current without puncture. He urges the trial of electricity in all cases aside from abscess, prior to laparotomy.

Results of Electricity in Extra-uterine Pregnancy.—The subsequent history of fifty cases of ectopic gestation treated by electricity are narrated in the *American Journal of Obstetrics*, No. 2, 1890. Twenty-three remained in good health out of one section numbering twenty-five. Ten per cent. of the other division had died; in seven a small tumor remained. Suppuration had not occurred in any. Rupture of the sac did not result in any. Puncture is condemned. He gave no opinion of the desirability of the method beyond decrying it after the third month.

In nine cases operated on by myself, the women all did well, without any complication whatever, the last being done three years ago at Westfield, N. J. Faradism was employed at very high strength as the fœticidal agent, and galvanism was used subsequently to procure absorption, *which it did positively and completely.* The diagnosis was made in every instance by at least two physicians in addition to my myself, and in each case expert opinion was consulted.

External Currents in Laryngeal Disease.—Dr. Th. Clemens considers the larynx as more readily accessible to electric applications than any other organ, and he suggests (*Therap. Monatshefte*) its use in syphilitic sclerosis, growing indurated papilloma, catarrh, and hyper-secretion. Intractable spasmodic cough gives way readily to Faradism, and transportation (galvano-osmosis) of medicaments is easily produced under galvanism.

Electric Light in Empyema.—Voltolini employs an incandescent lamp of low voltage (5 to 10) within the

mouth, the lips being closed. When the current is turned on, and the room darkened, the antrum becomes translucent—so he says; but if empyema be present the effect is not obtained. Heryng lays stress on this point as aiding diagnosis. I have not found the effect to follow buccal illumination in any of a number of experiments; but this may be because the Prusso-Germans are not constructed on the same models as Philadelphians (Megalocephalitis).

Electricity in Goitre.—Marand describes a case in which alternate electrolysis and Faradism produced complete cure of a large goitre, which, however, was not associated with exopthalmos. Negative puncture was employed, and recovery ensued in six weeks.

Elephantiasis Treated by Electricity.—Silva Aranjo refers to the value of this agent in the disease named, and from an experience of many years in Rio Janeiro, comprising over four hundred cases, he relies on electricity as an efficient aid to other measures in any case, and as a specific in many. He claims absolute cures in a number of instances.—(*Atlas des Malades de la Péan, 3 fas. 1889.*)

Treatment of Cancer by Electricity.—Dr. Inglis Parsons writes to the *British Medical Journal* to say that usually: in his experience, the repetition of electric treatment is unnecessary. His only reason for operating more than once in any case was because the growth was too large to be gone over at a single sitting. He takes the ground "that cancer is probably due to an escape of healthy cells from the control of the nervous system," as stated in the journal quoted, on April 27, 1889.

Application and Action of Electrolysis on Solid Tissues.—This is the preferable method when one wishes to act on subcutaneous tissues without injury to the skin. Kuttner has used this method in nine cases of struma, with the result that two were cured and five were very much improved. Electrolysis is best adapted to the large, soft, strumous tumors, and twenty or thirty séances of ten minutes' duration, repeated every two or three days, generally suffice to cure. It can be used in naso-pharyngeal tumors, and in enlarged prostate; but as relief in the latter is generally needed immediately, this method can be used only when there is no hurry. Where it is not necessary to spare the overlying tissues, electrolysis has no advantage over the knife. In the treatment of naso-pharyngeal tumors, electrolysis is unrivaled. By this method the prognosis is favorable, while removal by other methods give 50 per cent. mortality. Stricture of the urethra is helped by it, but further experiments are needed in the case of thyroid tumors. It is especially adapted to local absorption or destruction of tissue, and in the latter respect is on a par with the galvano-cautery of Paquelin. The latter may be quicker and more intense in its action, but the former is easier to control, and does not destroy so much tissue.—*Deut. Med. Zeit.*

Injury to the Ear by Telephones.—M. Lannois, of Lyons, states that the healthy ear is not injuriously affected by this instrument, but that in any diseased condition varied troubles are causable, such as tinnitus, subjective noises, deafness, etc. These difficulties may disappear, from accustoming the ear to the phone, but at times not. They do, however, always when the apparatus is discontinued.

Injury to the Eye by Lightning-stroke.—Buller (Arc. Opthal. xvii. 2) reports a case in a young woman in whom nothing abnormal externally appeared. The pupil of the left eye did not respond as quickly to light as the other. Refraction was hypermetropic. Right eye V normal, left eye $V\frac{6}{15}$. Insufficiency of external recti due to probable injury. There was opacity in the left lens posteriorly, but not as in polar cataract. There were also floating opacities. Retina very pale. Vessels diminished in calibre. Circumvasculitis retina, choroidal pigmentation and dull orange-colored spots. Color sense impaired.

Uterine Electrode.—Dr. Eliza M. Mosher, of Brooklyn, N. Y., has devised an electrode, the intra-uterine portion of which is leaf-shaped, and she depends on this particular shape as a means of replacing versions. The instrument is made by Messrs. Haslam & Co., of Brooklyn, and it is illustrated in the *N. Y. Medical Journal* for June 22.

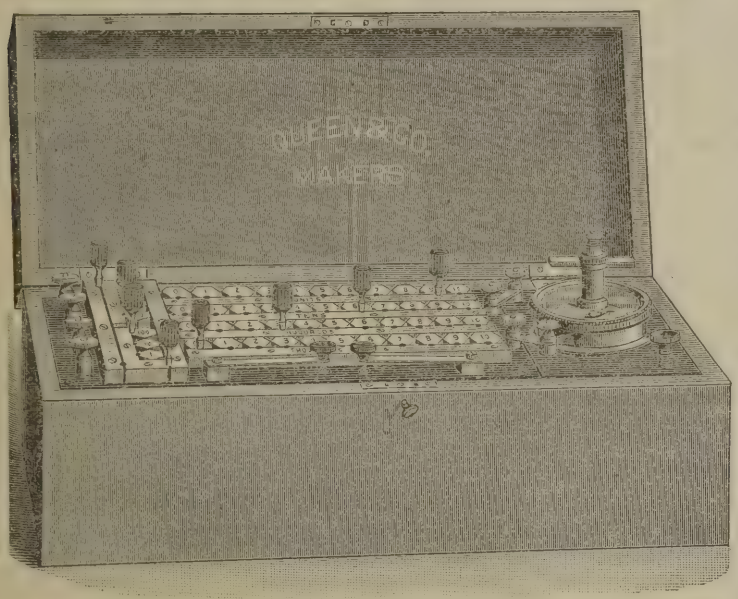
Chloride of Silver Elements.—The dry cells now produced by the Barrett Company are an improvement over the wet cells, and it is said that they wear longer. An important precaution is to be noted, however, viz., that argentic chloride is dangerous under certain conditions, and short-circuiting in the group of cells by metallic connection directly on the row of pins (on the number board) *may* cause explosion. Make a note of this in your memory. Other makers are adopting these elements.

The Phonograph in Medicine.—The phonograph, or graphophone, is suggested as a universal acoumeter by Lichtwitz, of Bordeaux, being superior to the watch, the tuning-fork, or the human voice, unless the latter is trained in all its inflections. Expert declamationists would be needed to prepare the cylinders.

New Portable Testing and Resistance Sets.—Our illustration shows the new portable testing and resistance set, now made by Messrs. Queen & Company, of Philadelphia. The best and most complete of the series is shown in Fig. 1. It is designed for work where considerable accuracy is required. The coils in this set are arranged in four rows, each row being made up of ten coils of the same denomination. The blocks in each row are numbered from left to right, and from zero to ten, while the longitudinal bars underneath have engraved upon them the denomination of the coils of that row. The connections of the coils are such that but one plug is required for each denomination. By inserting it in any block as many coils of that denomination are thrown in as may be indicated by the particular number engraved upon the block; thus, as the cut represents it, there are in circuit 369 ohms, *i. e.*, no thousands, three hundreds, six tens and nine units. Another special feature of this set is the arrangement of the bridge arms which are seen at the left; these are combined with reversing bars, so that the proportional arms may be instantly interchanged, an operation which is absolutely necessary in many special methods. An additional advantage is that but six coils are necessary in the bridge, instead of eight, as usual, to get the proportion of one to one thousand, or one thousand to one, thus making the set smaller and more portable. The bridge coils are one, ten, and one hundred on one side, and ten, one hundred and one thousand on the other. To effect this reversal two plugs only have to be changed. This use of the reversing arrangement in testing sets is said to be original with Messrs. Queen & Company, it having never before been employed except in the most expensive and elaborate laboratory instruments.

The coils are wound of the now famous platinoid wire, which has a very specific resistance, changing by but .0023 per cent. for each degree centigrade of temperature variation. They are adjusted by Professor Wm. A. Anthony to an accuracy of from one-fifth to one-tenth of one per cent., while the bridge arms them-

selves are adjusted to a still higher degree of accuracy. The galvanometer is a successful adaptation of a laboratory instrument to the needs of portable work, and is one of the most sensitive, complete and portable instruments ever combined in a set of this character. The wire is of several hundred ohms resistance, and is wound so as to have a maximum effect upon the needle; the needle itself is an astatic one and delicately suspended by a very fine cocoon fibre, so that there is practically no resistance to any deflecting force. By means of a very weak controlling magnet, sliding upon the suspension tube, the needle can be made almost perfectly astatic, and will show an appreciable deflection for currents as small as from $\frac{1}{3000}$ to $\frac{1}{5000}$ of an ampere; the brass box containing needle and coil is movable about a vertical axis, so that the needle can always be brought to zero, whatever the position of the box as a whole. The whole galvanometer lifts out of its position in the case, and can be used independently or in connection with other apparatus if desired, three leveling screws being provided for leveling when so used. By closing the cover of the box the weight of the needle is automatically taken from the fibre, and the latter protected from injury. The battery and galvanometer key are seen in the front of the box, and are independent of each other. The whole is mounted in a polished mahogany box, with leather handles and lock and key, and measures, when complete, but eighteen inches long by six and one-half inches broad.



Improved Law Cells.—The latest style of this cell is probably better adapted to the use of physicians than any other. It is greatly preferable to anything in the shape of dynamo currents, as being more readily controlled by those unaccustomed to high voltage, and much more inexpensive.

CREASOTE is being supplanted in the treatment of phthisis by benzosol, or benzoylortho-oxyanisol. This is a colorless powder, with little odor and taste, insoluble in water, soluble in ether, chloroform and hot alcohol. Walzer has used it in daily doses up to thirty-six grains, in powders or chocolate pastilles. No unpleasant symptoms were observed, but very favorable results obtained. He pronounces benzosol an agreeable and harmless substitute for creasote.

—*Provincial Medical Journal.*

A PLEA FOR THE MORE FREQUENT USE OF CHLOROFORM IN OBSTETRICS.[1]

BY J. F. BALDWIN, A.M., M.D.,
COLUMBUS, OHIO.

FROM the time of Sir James Y. Simpson, of blessed memory, to the present, there have been obstetricians who have persistently urged the use of anæsthetics in labor. But the profession in general, with its inherent conservatism—a word that not infrequently is simply an euphemism for stupidity—has failed to be convinced, and here, as elsewhere, it must be by line upon line and precept upon precept that the desired end can be secured. I can add no new arguments nor statistics. Our own Reeve has exhausted all these. But, perhaps, I can add a little to the momentum which others have secured, and thus aid, though ever so slightly, in diminishing the agony of parturition.

I shall speak of chloroform alone, since ether is too slow in action, too irritating, and too inflammable, for obstetric work, while we have all, doubtless, been disappointed in chloral, cocaine and antipyrine. If any anæsthetic is to be used, chloroform is beyond question the one to be employed.

Let me give a case or two to illustrate:—Mrs. B., American, aged twenty-four years, primipara, of fine appearance and excellent health, but having a high strung nervous system and being very sensitive to pain, was confined under the care of two most excellent Columbus physicians. She was in labor many hours; the pains were hard, and, to her, agonizing. The pelvis had a somewhat contracted outlet, necessitating the use of the forceps, but no chloroform was given. The instrument was used by first one and then the other of the two physicians for over an hour before delivery was finally accomplished. The exquisite agony that that poor girl suffered can only be imagined; no words in any language can adequately describe it. The shock was great and convalescence retarded. For two weeks she could not fall asleep without the horrors of that occasion coming over her, like a terrible nightmare, and arousing her from slumber.

Two years later, I was called upon to attend her in her second confinement. The first stage was long, twenty eight hours, but the pains were borne bravely. When the second stage came on, chloroform was administered as needed. When it finally became evident that the forceps would be required, the chloroform was pushed a little more, the patient swung into position, and the child delivered after a somewhat prolonged effort. As soon as the child was born, the chloroform was removed, the placenta expelled, and the patient made dry and comfortable. She then became sufficiently conscious to be told that all was over, and that the child was of the desired sex, when she smiled delightedly, rolled partly on to her side and dropped to sleep. After sleeping for two hours, she awoke happy and comfortable; with no nightmare dreams of horror, and with no unpleasant recollection of the ordeal. This lady's husband was present on both occasions; he is a muscular Christian, and he would be a bold doctor who, called on any future occasion, would refuse to give her chloroform.

---

[1] A paper read before the Ohio State Medical Society, June, 1890.

Another patient I have delivered of her three last children under chloroform, her two first having been born under the charge of other physicians and without chloroform. Her praises of the second method are unstinted and heartfelt. She has not had the feeling of post-partum exhaustion which she formerly experienced, and convalescence has been more rapid.

I report these two cases, not because they are unique, but because they are typical and show the marked contrast between the two methods.

I have carefully-kept statistics of over six hundred confinements. I did not give chloroform very frequently during my earlier years of practice, but I find I have given it in nearly thirty per cent. of the last three hundred cases, and in nearly sixty per cent. of the primiparous cases, and that the frequency of administration increases with each year.

We seldom need, in obstetrics, full surgical anæsthesia. I give my patient a folded handkerchief, and direct her to hold it out to me as soon as she feels the first indications of an oncoming pain. I pour a few drops, twenty or thirty, of chloroform upon the handkerchief, she claps it to her nose and inhales quickly and deeply, through both nose and mouth, three or four times. By this time, the pain is fairly on, but its keen edge is banished by the anæsthetic; she holds her breath and bears down, and then, as the pain passes away, drops off into a restful doze. This process is repeated as long as necessary, except that towards the last, at the supreme moment of agony, when the head is distending the vulva, I frequently push the drug to the surgical degree. For turning, or instrumental delivery, I always give full anæsthesia; except in the case of women, chiefly foreigners, having relaxed soft parts, capacious pelves, and nerves that seem to have no pain filaments; for such, anæsthesia is an unnecessary refinement.

Four objections have been offered to the use of anæsthetics in labor:

1. The pains will cease, and the labor come to a stand-still. I have seen the pains thus held in abeyance for fifteen or twenty minutes; but, at the end of that period, they would return with full force and the labor proceed. In case, however, they should not return, it would of course be necessary to withdraw the chloroform, and for it substitute condolence with the patient over her unfortunate idiosyncrasy.

2. Uterine contractions will be less vigorous, and we lose the voluntary contractions of the abdominal muscles; hence the labor will be prolonged. If only obstetric anæsthesia is produced, if we stop short of surgical anæsthesia, neither of these conditions will result. But, on the other hand, by the anæsthesia we secure a high degree of relaxation of the muscles of the perineum, and more or less yielding of the circular fibres of the cervix, and thus greatly reduce the resistance to be overcome. We thus, ultimately, gain more than we lose.

3. The child will be seriously affected. This is an old objection, long since refuted. No such result has ever been reported, and the objection has no physiological foundation.

4. We increase the danger of post-partum hemorrhage. I have said that I usually carry the anæsthesia to the full surgical degree just as the head is being born. I have never had a case of post-partum hemorrhage.

Fordyce Barker has given this matter special consideration, and expresses himself as follows: "I am strongly convinced that chloroform does not promote post-partum hemorrhage." He administered it in several thousand cases, and the only hemorrhages occurred when no anæsthetic was given.

In 1877, Dr. Wilson, of Baltimore, reported that he had given chloroform between two and three thousand times, during twenty-eight years of practice, without a single case of post-partum hemorrhage, or the slightest ill-effects following or attending its administration.

5. The inherent dangers of the chloroform itself. There is no drug, of any real virtue, in our entire materia medica, that can be administered to a lying-in woman with as much relative and absolute safety as chloroform. Whether this immunity is due to the cardiac hypertrophy, to the cerebral congestion, to the physiological antagonism of the pain itself, or to something else, or to some two or more of these conditions, I do not know. But no fact in medicine is more clearly established than that this immunity exists. Chloroform has been given to hundreds of thousands of lying-in women, and the records may be challenged to authenticate a single fatal result when the drug was administered by a physician.

There is no higher authority, in this matter, than Dr. J. C. Reeve, of Dayton, Ohio. Dr. Reeve has most conscientiously run down every reported fatal case, and finds but a single one in which death resulted when the chloroform was administered by a physician, and, as in this case no autopsy was held, the real cause of death is left in doubt.

But suppose we place on the debit side a dozen deaths, or two dozen, if you will; how many lives saved shall we place on the credit side? The tenderly reared, nervously organized girl, who, after enduring ten, or fifteen, or twenty hours of the pains of the first stage, is then compelled to endure for one, or two, or three hours, the inexpressible agony of the second stage, is not only exhausted, physically, mentally and morally, but really suffers from a high degree of shock, and is in no condition to withstand the inflammatory reaction or the insidious septicemia of her lying-in. And there is no doubt that hundreds of such women have been saved by the conservative effects of anesthesia.

Chloroform not only relieves pain, and thus prevents, to a large degree, shock and exhaustion, but it also, by its relaxing effect on rigid os and perineum, hastens delivery and also diminishes greatly the liability of these organs to laceration. I have more than once found a primiparous patient well advanced in the second stage, with pain almost continuous and agonizing, bearing down efforts uncontrollable, perineum bulging almost to bursting, but with vulva undilated and resisting. These are the cases that give us central perforation of the perineum, and here chloroform shows its power. Under its influence the bearing down ceases, the perineum and vulva relax, and the catastrophy is averted.

My obstetrical triad is as follows:

During the first stage of labor, morphine.

During the second stage of labor, chloroform.

During the third stage of labor, nothing.

Summary.—Chloroform relieves pain.

It shortens labor; usually.

It prevents shock.

It prevents nervous and physical exhaustion.

It reduces the liability to rupture of cervix and perineum.

It does not conduce, in any material degree, to post-partum hemorrhage.

It does not effect the fetus.

It is absolutely safe, when properly administered.

Contraindications.—1. Such conditions of labor as lead the obstetrician to believe that he may, at some

supreme moment, require all the woman's voluntary efforts to assist him. Such conditions are very rare.

2. Fatty degeneration of the heart; though if we accept the conclusions of the Hyderabad Commission, even this may not be a contraindication; and the disease is practically never diagnosticated, except *post-mortem.*

Brain disease is not a contraindication. An epileptic is better off with than without chloroform. Lung disease is not a contraindication; not even advanced phthisis, according to Lucas Championniere. With kidney disease, chloroform is clearly indicated. As to heart disease, Parry says: "Diseases of the heart are no contraindication to the use of chloroform," and Bordeau uses almost the same words. Augus McDonald, in his book entitled The Bearings of Chronic Diseases of the Heart upon Pregnancy, Parturition and Childbirth, says: "If chloroform be properly administered, I think it cannot but be useful in all cases." He thinks that the straining and suffering are far more dangerous than the chloroform. Fordyce Barker says: "Disease of the heart, lungs, or kidneys, is an additional reason for resorting to anesthesia in midwifery, as the vital forces are thus saved rather than exhausted." And even in fatty degeneration of the heart, Dr. Snow, the eminent authority, says: "A person is more likely to recover with chloroform, if the pain be severe, than without it."

In conclusion, I cannot do better than reproduce the vivid word-painting of Dr. W. H. Mays, of San Francisco, in an article written nearly ten years ago:

"Pain is, even when viewed scientifically, only a potent evil. Pain is a disease itself, lighting up in the economy its own set of consequences. Unchecked, it goads the nervous system to madness, and pyrexia ensues, with functional and organic disturbances. The whole duty of medicine may be summed up in two requirements: First, to remove pain; second, to prevent it. Opium, which deadens pain, is the most valuable of all drugs; rather than lose it we could afford to part with all the rest of materia medica besides. Chloroform, which also produces insensibility to pain, initiated in its discovery a new era in surgery. Yet there are physicians who, while they never hesitate to prescribe an opiate in cases of severe suffering, who never perform an operation without first anesthetizing the patient, yet will stolidly watch, hour after hour, the agonized throes of a woman, and stretch forth no hand for her relief. The tortures that women often endure in the process of parturition are beyond conception—at least beyond our conception. Take the case of a newly-married girl, gentle, tenderly reared, and fragile as a flower. Of suffering, of endurance, she knows next to nothing; her life has always been shielded by loving care, her wishes gratified, her whims indulged. As is the case with so many American girls, her nervous organization is highly developed, her sympathetic system hypertrophied. She finds herself confronted with childbirth. At the first onset of pain, the little barrier of fortitude she has built up for the occasion is swept away and she is taken possession of by a terror that her panic-stricken brain fails utterly to control. There is no escape! While one pain is holding her in its terrible grip, she knows the next will be yet worse, and the interval is spent in frenzied anticipation of still greater sufferings to come. With nerves strung to a fearful pitch of tension, and reason dethroned by fright, the poor sufferer writhes this way and that, and shrieks in wild despair, 'O let me die! I would rather die than endure this.'

"Throughout this scene the old fashioned physician preserves an unruffled demeanor, and tries to comfort the wretched sufferer with stereotyped phrases; tells her in pitiful mockery, to 'try to rest between the pains;' or reminds her, with specious reasoning, that 'all women have to go through the same,' and withholds in the very acme of physical suffering the blessed unconsciousness that he willingly supplies for the mere drawing of a tooth or lancing of an abscess."

ATRESIA OF THE EXTERNAL AUDITORY MEATUS.

By SETH S. BISHOP, M.D.,
CHICAGO, ILL.
Surgeon to the Illinois Charitable Eye and Ear Infirmary.

AMERICAN medical books on the ear contain so little on the subject of congenital and acquired imperforation of the external auditory canal, that it appears fair to infer that this anomaly is of uncommon occurrence in this country.

Only the following four cases of complete and permanent imperviousness of the external meatus have come under my observation during a practice of fourteen years, eight of which have afforded me quite a respectable experience in hospital and dispensary work.

CASE I was a man thirty-two years old, who applied for treatment August 15, 1883. Several years previously he had been run over by a railroad train that severed the auricle from the head. The surgeon in attendance is said to have had no hopes of the man's recovery, but severed the auricle to the side of the head to make the subject appear more presentable at his funeral. The result was that union of the parts took place in such a manner as to completely close the external canal, and deprived the patient of any use of that ear. However, the fact that the auditory nerve had retained its integrity was established by a careful application of the hearing tests. I therefore cut away the scar tissue sufficiently to obtain a channel of nearly the natural size. There was only a slight discharge following the operation, and when the patient left the city for his home, two weeks later, his hearing in that ear was good for ordinary conversation.

The result showed that the drum, and auditory nerve had been uninjured by the accident, and nothing was needed to restore the usefulness of the organ beyond opening the door for the admission of sound.

CASE II.—A girl eight weeks old was brought to my clinic October 10, 1885. There was a congenital deformity of one auricle, and absence of the external auditory meatus of the same ear. The auricle was rudimentary and doubled forward upon itself. It appeared shrunken and pinched, and had a large, hard nodule and several indentations in that part of the helis that corresponds to the keystone of an arch.

It is interesting to note in this connection that the mother attributed the deformity of the auricle to the fact that about the fifth month of gestation her elder child bit the mother's ear severely at just that point that corresponds to the greatest auricular deformity in the baby.

At the point where the canal ought to have been there was a depression, or cul-de-sac, that yielded to pressure and imparted an impression as if there were an opening in the bone beneath.

Four months later, careful tests led me to believe that the child could hear with that ear. I operated to correct, as far as possible, the deformity of the

auricle and to ascertain if there were any bony meatus. On cutting down into the depression where the canal should have been, I found nothing but a depression in the bone. No bony canal could be found, and I did not consider that further operative interference was justifiable. A sufficient opening was maintained, however, to give quite a respectable appearance of an external meatus.

CASE III was an infant, fourteen months old, healthy and apparently normal except in respect to one ear. There was no opening where the external canal should have been, and, although the patient seemed to hear on that side, the parents were unwilling that an exploratory opening should be made. I saw this case several years ago, but have never heard from it since.

CASE IV was a locomotive engineer, thirty-two years old. At the age of three years he was run over by a wagon that detached the auricle and tore off a part of the cheek. The auricle was stitched over the meatus and completely closed it with dense fibrous tissue. The patient stated that he had never since been able to hear with that ear, but the tests showed that the nerve was sensitive to sound.

About ten years ago he suffered intense pain in this ear for two weeks. There followed a purulent discharge from a pin hole perforation in the adventitious tissue at the highest point of the mouth of the meatus. The discharge has continued ever since, being copious and mal-odorous. The exit for pus was so minute that accumulations produced considerable pain. At such times he pressed above and in front of the ear, and alternately pulled and pushed the auricle in a sort of pumping process, to work the pus out. He succeeded in this manner, and by the aid of Valsalva's experiment, in evacuating the pus cavities.

I operated to open up the meatus, and found it filled with tough cicatricial tissue for about three-fourths its depth. After opening up the canal, and cauterizing it with chromic acid, I inserted a vulcanized rubber tube and retained it in position with antiseptic dressings.

After the operation he could hear my sixty-inch watch one inch, and ordinary conversation eleven feet distant. After several treatments with the Eustachian catheter and topical applications, the patient resumed his occupation. When he returned again the canal had contracted, and granulations had extruded the rubber tube by one-half its original insertion. I then curetted and cauterized the canal and recovered the ground lost. Subsequently, however, the same experience was repeated and the canal was allowed to close, but by this time the discharge had diminished to a few drops in the twenty-four hours, and the foul smell had disappeared.

I had already been dilating the old perforation. Through this I could pass a probe upward into the mastoid cells and inward parallel to the roof of the external meatus to the tympani attic. I proposed a more radical operation for the excision of all the occluding tissue which would enable me to discover and remove any carious bone that might be present, but he was so well satisfied with the almost complete cessation of the discharge that he refused, and returned to his vocation.

After dilating the original opening, we found that he retained his hearing nearly, though not quite, as well as it was through the vulcanite tube.

The remarkable circumstance in this case is that the perceptive apparatus and the conducting mechanism should retain their functions after twenty-nine years of apparent disuse. But I apprehend that, although the patient was unconscious of any hearing power in this ear, it was sufficiently responsive to sound-vibrations of a major character to give the conducting apparatus exercise and to keep the nerve sensitive. The nature of his business lends color to this view, for its environment abounded in vibrations which would be imparted to every organ in his body. If anything in nature is competent to arouse a dormant acoustic nerve, I should say that nothing but Gabriel's trumpet would surpass the clanging of bells and the hooting of whistles.

Certain authors speak of imperforate external auditory meatuses as though they might be of frequent occurrence, but among the records of the Illinois Charitable Eye and Ear Infirmary, in Chicago, embracing more than eight thousand cases of diseases of the ear, I find but one case of closure from exostosis, three cases of congenital absence of the meatus auditorius externus, and three of acquired atresia from traumatic causes. Of course, we have found numerous cases of narrowing and various irregularities of the canal from causes that are common.

A reference to the following authors will bear me out in my inference that congenital and acquired atresia of the external auditory canal are anomalies of infrequent occurrence in America.

Roosa mentions congenital absence of the meatus, but does not treat of traumatic closure. He records no operations to form an external canal.

Burnett speaks of the possibility of closure, but cites only membranous and osseous neoplasms as the cause. None of my cases were of that kind, two being congenital and two traumatic.

Green's edition of Schwartze speaks of congenital atresia and stenosis of the meatus as "specially frequent."

Turnbull mentions congenital absence of the canal and rudimentary auricle, but not as being frequent.

Mittendorf does not treat of the subject.

Jones ignores it.

Pomeroy does not treat of it.

Sexton's book on the ear is silent on the subject.

Von Troeltsch has seen congenital absence of the meatus, speaks of the difficulties of the operation and discourages it, except one can with certainty find the bony canal.

Buch has nothing on the subject, but mentions membranous closures.

Congenital cases have been reported by the following authors: Politzer, Moos, Knapp, Jäger, Welcker, Robb, Hessler, Zaufall, Steinbrügge, Zuckerkandl, and Michel.

Politzer's classical work on the ear advises an "operation in congenital atresia of the external auditory meatus only when it has been with certainty ascertained, by careful examination, that it is a case of congenital thin-walled septum at the entrance to the ear. When the atresia extends far inwards, so that the canal cannot be made out, or only a solid cord, operation must be avoided as irrational and dangerous."

Virchow's Archives, Bd. 30, S. 221, and Bd. 32, S. 518, says: "Congenital anomalies of the external ear and its neighborhood are to be referred to early disturbances in the closure of the first branchial cleft, and are often associated with fistulæ of the other branchial clefts, cleft palate and other forms of arrest of development in the facial bones, as, for instance, with unilateral atrophy of the face.

719 ADAMS STREET.

ANDEER recommends the local application in diphtheria of a 10 per cent. glycerine solution of resorcin.

ON MEAT-JUICE AND BOVINE BLOOD IN THERAPEUTICS.

By FRANK WOODBURY, A.M., M.D.,

Fellow of the College of Physicians of Philadelphia; Hon. Prof. of Clinical Medicine in the Medico-Chirurgical College of Philadelphia; Formerly Attending Physician to the German Hospital of Philadelphia, etc.

IF Dr. Sangrado might be taken as the type of the physicians of the preceding century, when depletion was the sheet-anchor and blood letting a most sovereign cure for an inward bruise, as well as almost every ill that flesh is heir to, the English physician, Dr. Graves, who "fed fevers," may fittingly represent the therapeutic idea of the present age, which may be regarded as pre-eminently the era of restorative medicine. This change of treatment is partly attributable to the lessons of experience, which demonstrated the danger or uselessness of bleeding in many diseases for which it had been formerly practised—a glaring illustration being venesection in the treatment of pulmonary consumption,—and, perhaps, even to a greater degree, to increasing knowledge of the nature of morbid processes and the physiological effects of remedies. Furthermore, it must be remembered that a large proportion of our patients are no longer full-blooded, robust country squires and their families, but the highly nervous, often anæmic, dwellers in cities and their offspring.

Whatever may have brought it about, there is no denying the fact that at the present day our patients cannot bear the loss of blood, which figures so prominently in the clinical records of the past century, and even the first half of the present. Blood-letting is indeed what it was designated by Gross, "a lost art;" it is now performed only in a medical emergency similar to that which would warrant the amputation of a limb by a surgeon, and performed in the same spirit.

The therapeutic problem which now confronts us in the majority of cases is, How to increase the blood-supply? In pernicious anæmia, in phthisis and other chronic wasting diseases, in exhausting discharges, in blood-poisoning, we are called upon to improve the quality of the blood and increase its quantity; and to accomplish this various methods are followed. The most direct method is by transfusion—a method which has been practised for centuries, but it must be confessed without very satisfactory results, except to tide over some critical period, and for its temporary influence as a vital stimulant. This method is inconvenient, requires some skill, and calls for special apparatus for defibrinating the blood, keeping it warm, etc. In the first place animal's blood will not answer; the failure of the experiments of Gesellius with lamb's blood may be considered as settling this definitely. In the second place, it is doubtful whether defibrinated human blood possesses any marked superiority, for the purpose, over goat's milk, or even warm saline solutions, such as employed by Hingston, of Montreal, with success in the collapse of cholera. Apart, then, from the cases where the blood transfused is mainly useful in distending the vessels, and suddenly adding to the pabulum in the circulatory system, there is no real advantage, but many obvious disadvantages, in resorting to this method of increasing the quantity of the blood, by administering easily assimilable food and remedies favoring constructive metamorphosis. Enamata of bullock's blood have been used, and blood has been thrown into the peritoneal cavity with a view to its absorption. Experience has shown that the necessity for a resort to these methods very seldom arises; while the natural channel, the stomach, is capable of performing its functions. In Paris, we observe that it is quite the mode for fashionable ladies and their escorts to revive their energies by a visit to La Villette to drink the blood from the cattle, sold them by the butchers at thirty centimes the glass. When blood, or meat juice, is introduced into the body, it has already undergone changes, so that it no longer can be considered as blood in a living state, but simply as a nutritive material, which may, or may not, be acceptable to the digestive organs in the ordeal that fits it for assimilation. The blood is the life only so long as it is in a physiological state and under physiological conditions. It has, therefore, no mysterious life giving powers as a food, even when the patient goes to the abattoir and drinks the warm blood as it flows from the slaughtered beef; beyond the fact that it is a sort of fluid beef, chemically it is an albuminous solution holding certain salts, and among other principles a small proportion of a very soluble form of iron. In 1852, Dr. Samuel Jackson, of Philadelphia, conceived the idea of drying bullock's blood and administering it to his patients as a powder. Dr. F. E. Stewart more recently has carried this idea a little further by using only[1] defibrinated blood, and drying it in scales. At the suggestion of Dr. Andrew H. Smith, of New York, in 1879, who had also been engaged in investigating this subject, the following formula was used for administration of the dried blood to patients: Sanguis bovinnus exsiccatus, ʒvi; brandy and glycerine of each, fʒiij; dose, a tablespoonful. The dried blood was carefully prepared under the direction of Dr. Craven at the Jersey City Stockyards. The beef-blood only is used from healthy animals. Sheep's blood cannot be employed because of its disagreeable odor and its well-known tendency to convey the ovum of the tapeworm.

It has been found that the beef powder and elixir are acceptable to the digestive organs and are readily assimilated, so that their effects upon the nutrition of the body are rapidly made manifest. As Dr. Stewart justly claims, special care should be displayed in preparing blood for therapeutic use. It is exceedingly important that animals in prime condition should be selected for killing; that the blood should be immediately defibrinated as soon as it is drawn, and at once mixed with the other ingredients to preserve it, before it has had time to acquire any taint by exposure to the air. If the blood becomes at all tainted, as will occur in a few hours in hot weather, the product will be inferior, and should be rejected. In the article referred to, Dr. Stewart states that there are two preparations in the market based upon the formula of Dr. Smith, or resembling it; these are Murdock's Food and Bush's Bovinine. Of both of these I have some knowledge and some experience. The former I used for some time, but found a strong repugnance manifested by my patients to its odor and taste. Upon examination I came to the conclusion that their objections were well founded, and that the compound was more or less tainted, owing either to want of care in collecting the blood, or the absence of an antiseptic to preserve it. This objection does not hold against Bovinine, which I regard as a special food and not as a medicine, and, therefore, do not hesitate to order it when needed, because it is a proprietary article, as many special articles of food are, such as Bass's ale, or Cross and Blackwell's pickles. Owing to the alcoholic strength of the preparation, it is free from putrefactive odor,

[1] Hœmoglobin Compound or Bullock's Blood in Therapeutics, TIMES AND REGISTER, April 26, 1890.

and keeps well. The alcohol in some cases may be objectionable, as I have had patients with gastralgia and nervous dyspepsia, who could not take alcoholic preparations at all. In such cases, the addition of twenty or thirty drops of Bovinine to hot beef-essence or coffee was sufficient to volatilize the alcohol, and the bad effects were not noticed.

In cases of marasmus, in summer diarrhœa and apepsia, or feeble digestion in infants, I have seen excellent results from this agent in ten or fifteen drop doses added to each bottle just before feeding. In malnutrition of adults, neurasthenia, nervous dyspepsia, intestinal indigestion, and in wasting diseases generally, it is admirable in its results. I prefer to administer it in beer, or a bitter malt extract; but it has no unpleasant taste and may be taken simply in ice-water. Some years ago Dr. Ely, of Rochester, reported excellent results from the use of meat extract, obtainable extemporaneously by pressure (in a fruit press) from raw beef, in several cases of diphtheria, which is pre-eminently a disease of asthenia and depression, requiring stimulants and the introduction of food the most easily assimilated and most highly nourishing. In many cases of the essential fevers there occurs a time when nourishment is of more importance than drugs, and in such an emergency and at the beginning of convalescence, meat-juice, or bovine blood, as in the above formula, is invaluable.

In a case of gastric-hyperæsthesia and neuralgia, associated with possibly a latent ulcer, or an unsuspected gastric catarrh, the patient was entirely prevented from taking ordinary food for some four or five months, during which she was kept alive by teaspoonful doses of Bovinine, and one or two bottles daily of a very light malt-liquor. This was the most marked case occurring in my experience; but a number of others attest the value of the formula of Dr. Bush, as a useful addition to restorative medicine.

The preparations of Dr. Stewart have appeared more recently, and I have not yet tried them sufficiently to speak of their merits, although I can endorse the statement made by him in his admirable paper as to the value of bovine blood in therapeutics when intelligently administered and combined with the usual magistral and hygienic treatment of the patient.

ANTISEPTIC MIDWIFERY.

By F. O. DONOHUE,
Mem. Med. Staff St. Joseph's Hospital, Syracuse, N. Y.

THE frequent repetition of homely truths often serves the better to impress them. The route which I am to pursue is a broad highway worn by the tramp of many feet, and when the history of the progress of science as applied to medicine in the last half of this century shall have been written, I doubt not antisepsis as applied to midwifery will receive honorable mention.

The theory and practice of antisepsis, founded by Lister, and now sufficiently justified by experience, that infection is brought about by the action of germs which float about us in the surrounding atmosphere, and which find entrance to the system through recent wounds and lacerations; the great reform in surgery, brought about by the antiseptic treatment, could not fail to have a deep influence on the complications of parturition, and the beneficent results of the application of antiseptics in parturition are too striking to be controverted. It used to be considered, with reason, that it was safer for a woman to be delivered in the most miserable hovel, in the most unsanitary surroundings, than in the most elegantly appointed and well regulated hospital. Now, under antiseptic precautions, there is almost complete immunity from septic disturbances in these institutions.

In Germany, I am credibly informed, the use of antiseptics in midwifery is enforced by law. It is the custom in that country, for all classes, to be attended by midwives; the services of the physician are dispensed with, except in complicated cases. Every midwife is obliged by law to provide herself with and carry all necessary appliances for antisepsis. If she fails to use these appliances, she is amenable to the law and is liable to punishment for negligence. In Germany, therefore, the consensus of medical opinion is in favor of antisepsis, carried out in detail; and, in looking over the statistics of the great maternity hospitals of Europe, as well as those in our own country, it is hard to conceive how there can be any difference of opinion on this subject. I am opposed, generally speaking, to the quoting of statistics to prove any premises, but the great reduction in mortality in these institutions, since the introduction of antiseptics, is so startling that their usefulness cannot be gainsaid.

Sometime about 1850, when the immortal Semmelweiss was interne in the great lying-in hospital of Vienna, assistant to Professor Klein, the mortality from puerperal fever was something frightful, reaching to fifty or seventy per thousand. It is related of Semmelweiss that the frequent ringing of the bell outside his door, every time the priest came to administer the sacraments to the dying, filled him with horror and roused in him a strong determination to find the cause of this fearful mortality. He noticed that women who were delivered before reaching the hospital escaped; he further noticed that all protracted cases to which the students had free access terminated fatally. About this time, a friend of his died from a dissection wound. The symptoms of his illness were like those of the puerperal cases. This gave him the clue. He soon set forth his views, and ordered all the students in his clinic to disinfect their hands and arms with chlorinated solutions. The mortality at once fell. His views met with great opposition, like those of all great innovators. It is said that his mind gave way because of the bitter opposition which his views encountered. He became an object of dislike and ridicule, but he accomplished a great work. He was the first to explain the true nature of puerperal fever: that it is nothing more or less than puerperal septicæmia, and his name will go down the ages as a great benefactor.

We are all familiar with the analogy which Sir James Simpson, of Edinburgh, described about this period, between the stump after an amputation and the internal surface of the uterus after parturition. He described the analogy between surgical and puerperal fever.

Evidently, the minds of these two great men ran in about the same groove at about the same period.

The one died an object of ridicule, with his reason dethroned; the other has to his memory a life-like bust in a prominent niche within the hallowed precincts of Westminster Abbey with England's illustrious dead, being the only physician whose memory has thus been honored.

Some years after this period the active part which micro-organisms played in the production of septicæmia furnished the key to the situation. The theory of the propagation by personal contact was soon pro-

mulgated. The manner in which the disease followed in the footsteps of some practitioners, and became the scourge of lying-in hospitals, the fatal results of cadaveric contamination, and the almost complete immunity from disease of women who were confined unattended, or on whom no examinations were made, and the lowering of the mortality which followed the use of disinfectants, all these things were after awhile explained.

The progress of bacteriology has shown that aseptic midwifery means scientific cleanliness, that is, on the part of the persons attending the patient, as well as the patient herself. It is interesting to note that seventy-eight examinations of the impurities under the finger nails were recently made in the bacteriological laboratory of Vienna, and the cultivations thus produced showed thirty-six kinds of micrococci, eighteen bacilli, three sarcinæ, and various other varieties. The removal of all such impurities is an absolute duty in all who come near a parturient woman. It is not enough to apply some antiseptic material to the surface of dirt, the impurity should be removed first, the hand antisepticized after.

Many obstetricians openly repudiate the antiseptic treatment as commonly practised, nevertheless contrive to obtain results up to the average, and this, no doubt, is due to the fact that the essential feature of antisepsis is perfect cleanliness, which is, after all, the most powerful antiseptic we can employ. Cleanliness of atmosphere, person, and instruments, with it chemical antisepsis, the use of which is not unattended with danger, may be safely dispensed with. There can be no doubt that the use of mercurial solutions in the lying-in room is attended with danger, and it is by no means satisfactory to find so many physicians using this drug so freely when milder measures would suffice.

To wash out the vagina with murcurial solutions after a normal labor is meddlesome midwifery, in my judgment. If the hand has been introduced, or after a prolonged instrumental delivery, where injuries have been sustained, giving rise to foul smelling lochia, then antiseptic solutions of mercury or carbolic acid are indicated, and should be used even then with caution. The management of the third stage of labor is very important from an antiseptic stand point. To ensure the complete expulsion of the placenta with its membranes, thereby checking any tendency to the decomposition of placental *debris*, to see that all clots are removed from the vagina, and to carefully inspect the perineum, and repair, if need be, any rent that may have taken place, thereby closing the avenue of entry for germs. To wash the vagina with injections of sterilized water, thereby maintaining cleanliness, and to withhold chemical agents, unless there be clear indications for their use.

DR. AND MRS. DE FOREST WILLARD were the only Philadelphia passengers on the "Teutonic" on her quick trip across the ocean.

WHERE colchicum, blue pill and salines are now employed with advantage, the same good results could be obtained by bodily rest in a suitable temperature by means of fasting.—*Shearer.*

SOMETIMES nature only needs a little assistance at starting, and she will then do the bulk of the work herself. Shearer mentions a case of pleurisy, which had resisted treatment, until one ounce of the effusion was withdrawn, when resorption at once set in, and rapidly proceeded to completion.

4. It is useless to attempt to remedy the spinal distortion so long as its cause remains unrelieved.

5. The existence of chronic pain in the sciatic nerve, not yielding in a reasonable space of time to medication, should always lead the practitioner to make a careful examination of the spine and of the region of the ilio-sacral juncture.

6. This affection is met with more frequently in adult than in child life.

7. Its appropriate treatment consists in splinting the pelvis, and thus preventing motion between the opposing surfaces of the symphysis, motion not being its natural function.

8. For the same reason extension cannot be expected to produce the favorable results in this affection that we obtain from it in arthrodial joints.

9. The disease is often of extremely slow development.

10. Its first symptom is abdominal pain, whence it may readily be mistaken for peritonitis, ovaritis, cystitis, and the like.

11. This pain is principally referred to the side on which the injury exists.

12. The existence of severe unilateral abdominal pain, accompanied by little or no febrile action, should lead to the suspicion of the existence of this affection.

13. A mechanic may, by a happy chance, give temporary relief to a patient suffering from this disease; but, as he is entirely ignorant of its seat and nature, he is not, perhaps, the safest person to refer the patient to.

The Polyclinic.

NUMEROUS rumors appear in the public press that influenza has reappeared in various isolated localities. Several times my own patients have asked me if la grippe had not come back to Philadelphia, as there was a general prevalence of catarrhs. These attacks, however, are merely epidemics of ordinary catarrh. They are distinguished from influenza by the absence of marked depression, of aching bones, delirium and alarming symptoms generally, and by the want of any tendency to increase the weekly mortality. That these attacks are really epidemic catarrhs, and not simply due to changes in the weather, I am fully satisfied from a careful observation of the conditions under which they occur. It is quite probable that the influenza has left behind it an increased susceptibility to catarrhs, which may not wear off for some time.—*Waugh.*

CHINESE REMEDY FOR DIPHTHERIA:—

℞.—Anhydrous borax	42.50 per cent.
Borneo camphor	12. "
Powdered pearls	9.55 "
Native cinnabar	15.30 "
Basic acetate of copper	1.20 "
Charcoal and water	19.45 "

This is the analysis of a powder known as Sin-Seh, which is so popular in Java that the regular physicians are never allowed to treat diphtheria. The formula is found in the "Pent-Sau-Kang-Mou," a Chinese work on therapeutics over three hundred years old. Some specimens of the powder also contained ox benzoar, indigo, coptis root, licorice, urinary sediment, musk, amber, ginseng, gold leaf, or tabasheer; but the above is alone essential.

The powder is blown over the tonsils and pharynx by an insufflator, every two or three hours; occasionally applying a little in the nose.

The regimen is strict, and, with the exception that milk does not seem to be used, much as our own at the present day. The patient must remain in bed in a cool, well ventilated room, free from draughts. He is forbidden to take ice or iced drinks—we are only beginning to learn that nothing makes the mouth drier or excites thirst more readily than glaciation—butter, sugar, food cooked in fat, and fruits. He is to take rice boiled in water, eggs and fish, later on minced fowl with bread. He is to drink nothing but water which has been boiled and allowed to cool.

THE PRODUCTION OF IMMUNITY FROM TUBERCULOSIS.

WE have little sympathy with the feeling that a person must be supported simply because he is an American. On the contrary, if a fellow-countryman cannot hold his own in open competition with the citizens of less-favored lands, when all are placed on an equality at the start, we feel somewhat ashamed of him. But when one of our own people actually does a creditable piece of work, and his claims are ignored because he is an American, one's sense of justice as well as patriotism is aroused in opposition.

For a long time Dr. Samuel G. Dixon has been investigating the question of obtaining immunity against tuberculosis. Last October he suggested the method of producing immunity, in the *Medical News* of this city. The propositions then set forth by him were: That it is possible to obtain from tubercular material a substance, free from micro organisms, that can be attenuated and inoculated in living animals so as to develop in them the power of resisting the attacks of the tubercle bacilli; further, that if these bacilli are to be used for preventive inoculation, their virulence must first be moderated. Dr. Dixon also stated that he had already succeeded in establishing a certain degree of immunity in animals by inoculating them with cultivations of a peculiar type of the tubercle bacillus; and that by exposure to varying temperatures and conditions of moisture, pressure and food, he had succeeded in producing an alteration in the morphological characteristics of this bacillus.

In a brief note in the *Medical and Surgical Reporter* Dr. Dixon enumerates the possibilities in the way of explaining the production of this immunity. He says:

"It is quite possible that the organisms in the changed forms have not sufficient vitality to live in the animal economy, and, therefore, the only active portion of the matter injected is a chemical product carried in with the bacilli and which is poisonous to the ordinary tubercle bacillus. Or again, it is possible that the organisms themselves are antagonistic to the bacillus of Koch. It is also possible that this unusual form of bacillus produces, when in the animal economy, that which kills the tubercle bacillus. Or, we can believe it possible for this new form to consume that from the animal tissues necessary for the existence of the tubercle bacillus, and by a different metabolic process to form a product non-poisonous to animal life.

"From the fact that we all inhale tubercle bacilli daily, without contracting phthisis, except in odd cases where there is a predisposition, or where a great number of bacilli are taken into the system, we are inclined to believe that a change, either chemical or otherwise, must take place in the normal tissues before we can contract the disease. If this be so, we must aim at correcting that change, and it seems within the range of possibilities that such a correction might be brought about by a chemical substance, or by stimulating the tissues by micro-organisms, harmless in themselves, either through their degree of vitality or their kind.

"Be this as it may, it will probably be interesting to the scientific world to know that the results published last October have been uninterruptedly corroborated by a series of inoculations of the prepared virus into guinea-pigs, rabbits, and opossums, after which they have resisted matter so virulent that all animals not previously inoculated with the changed virus took on tuberculosis when inoculated with it."

It will be seen that this investigation was undertaken long before Koch's recent announcement, and, indeed, it is probable that Dr. Dixon's first paper suggested to Koch, and Grancher as well, the line upon which their own researches have been since made. It has been the reproach of bacteriology that nothing of practical value in the treatment of tuberculosis has resulted from Koch's discovery. We may now hope that this will be removed, since Dixon's results point to the true way of combating the disease, by studying the biology of the bacillus, and ascertaining nature's methods of restraining its multiplication, instead of hunting for a chemical germicide.

QUACKS AND THEIR METHODS.

IT is an undeniable fact that a clever quack will secure—we will not say earn—more money from his patients than the regular practitioner. Of course there are exceptions; but they are few.

It is also surprising to note the ease with which the unsuspecting public can be gulled; and, while allowing themselves to be imposed upon, cheated, and often permanently injured, still imagine themselves benefited. It is therefore due to the public at large, as well as the medical profession, that these quacks and their methods should be publicly exposed. For such a work the medical press is eminently fit; and THE TIMES AND REGISTER trusts that it may be valuable to its readers in this line, as occasion presents.

One of the most well-known medical firms, the advertisements of which may be seen in almost any daily paper, is that of Drs. McCoy & Wildman, the

catarrh specialists of Philadelphia, New York, and eight other cities. It was with a desire for knowledge that a member of our editorial staff (himself a physician) wended his way to the offices of Drs. McCoy & Wildman, on Chestnut street. It was 1 P. M., and the gentleman of color who responded to the ring informed our representative that the doors would be open at 1.30, and business begin at 2 P.M. "Ambulances at three!" was mentally subjoined.

Promptly at 1.30 our representative again appeared on the scene, and was given a well fingered brass tag with the letter A stamped upon it. He was shown into the rear waiting room, where about a dozen sad-eyed men were already seated. There were about thirty chairs in the room, and a commodious spittoon allowed for every two chairs. Female voices coming from the front room suggested that this was reserved for women. The class of patients was decidedly poor, belonging mostly to the laboring class. An attendant in the hall called out a number every few minutes, and the unfortunate victim would rise and answer the summons. In about fifteen minutes he would return with a flushed face, full of misery, make for a spittoon, and cough, sneeze, shed tears, blow his nose, gag, and expectorate to his heart's content. In about ten minutes later he would again be called out and given a few large bottles of medicine.

While enjoying these demonstrations, the participants in which were constantly increasing, our representative scarcely heard "Letter A" called by the attendant; but, stifling his emotions, went out, and was ushered to the second floor, where a physician with a smiling face was awaiting him. After having obtained a fictitious name and address and a correct age, the doctor asked whether the trouble was in the throat and nose. "Possibly it was," was the rejoinder; and then our representative gave the following symptomatology of coryza:

"Doctor, whenever I take cold, my head and nose gets stopped up; I sneeze and my nose runs. At those times, if I lie on my right side at night, my right nostril will become stopped up, and if I lie on my left side, it will get stopped up. Then my head usually aches at the same time. Mind you, Doctor, the funny part of it is that I'm not troubled all the time; but it's only occasionally, when I take cold."

This was delivered without a smile, and the "light of learning" wisely nodded his head.

"Are you Dr. McCoy?" was asked.

"No."

"Dr. Wildman, then?"

"No?"

His name was Coates, and his father had been a practising physician in Philadelphia for fifty years. Our representative remarked that he supposed a good many physicians were employed by Drs. McCoy and Wildman.

"Oh, yes," said Dr. Coates; "two men could not begin to attend to such a business as *this*."

Then Dr. Coates turned up an Argand burner on a student's lamp on the desk at his side, and proceeded to insert a large nasal speculum in our representative's nostrils. No head mirror was used, and consequently no light was reflected into the nostrils. Then the throat was similarly examined without light, by aid of a tongue-depressor, and the tongue inspected.

Our representative inquired as to the nature of his disease.

"You are in a bad way," said Dr. Coates; "you have a bad catarrh of the head, throat and stomach, and your liver is in a bad condition. It will take eight months of our treatment for us to cure you. We will charge you fifteen dollars for the first month and nine dollars for each subsequent month. For this we will supply you with an inhaler and all necessary medicines. I advise you *not* to delay treatment, as yours is a condition that will go from bad to worse, and delay might prove serious. I should like you to take a treatment now. Everything can be gotten ready for it down stairs in ten minutes. If you have not the money by you, I have blank checks right here."

It may as well be remarked here, that our representative was enjoying perfect health when examined; and that he neither has, nor ever has had, catarrh. At the time of examination both nares were clean and clear, and his throat perfectly normal. His tongue had been purposely slightly coated. His liver is far from faulty. After recovering from the shock of learning his moribund condition, he timidly asked Dr. Coates if a cure were possible.

"I don't think there is a doubt of it, sir," said Dr. Coates, and then filled out a card with hieroglyphics that defied reading, and gave it to our representative, urging him not to wait, but to begin treatment at once.

About two weeks later another call was paid to the offices of Drs. McCoy and Wildman. Again Dr. Coates was seen. The cost of the treatment was complained of and our representative's photograph offered in lieu of compensation. Dr. Coates seemed suspicious, and said that this would be no inducement.

"Why, I assure you that there are quantities of persons who come and *beg* us to publish their photographs and statements."

After a little further talk, Dr. Coates' fears seemed to abate, and he said:

"Well, if you wish to, you can give us your statement after you have taken the treatment—and your photograph; and I'll make the first month twelve dollars, instead of fifteen dollars, and the subsequent months seven dollars, instead of nine dollars."

A new card was then made out and given our representative.

The above needs no comment. We trust only that it may serve as a warning to the public—a warning which, coming from the physician himself, might be unheeded or misunderstood.

MR. HENRY MAUNSELL SCHIEFFELIN, of the well-known firm of druggists of New York, has recently died from fever, at Alexandria. He was a good example of the God-fearing, enterprising, self-made man, and he was one of those who took an active interest in the negro-emancipation movement. By his will Mr. Schieffelin leaves four thousand pounds to the American Sunday School Union.—*Hosp. Gaz.*

Annotations.

A VERY extraordinary circular has just been issued by a firm of Philadelphia opticians. In it they acknowledge the hurried and imperfect manner in which opticians examine their customers' eyes for glasses; recognize that in no case should the optician prescribe; confess that they have been doing this wrong thing, and declare their determination to refrain from such culpable conduct in future. In return, they coolly ask the ophthalmologists to prevent this repentance from costing the firm anything by extending it their patronage.

PROF. SAMUEL G. DIXON has resigned his chair in the University of Pennsylvania, and accepted one in the Academy of Natural Sciences, where he will continue his bacteriological researches. The department of hygiene at the university was practically created by Dr. Dixon, who was mainly instrumental in the collection of an endowment for it. Quite recently he published a paper upon medical education, which has attracted much attention. In it he spoke of the great importance of a high standard of morality in those to whom is entrusted the education of young men. All who know how prone young students are to take their teachers as exemplars, and to find in their actions excuses for the slips to which youth is so liable, will appreciate the justness of this demand for uprightness in the preceptor. The medical student does not attend college so much to acquire the facts of medical science, as to prepare himself for the station he is to fill in his active life; and we are old-fashioned enough to believe that one is not a worse physician by being a *good* man.

THE struggle for existence is sharpest in the great cities, where the greatest success is obtainable, and where a certain number of unfortunates are sure to be ground down very fine between the millstones. The handling of large sums to win a profit renders it difficult to make a similar profit out of small sums—especially as the proportional cost increases inversely with the amount to be invested. Now and then we get a glimpse of the substratum of wretchedness underlying the splendor of the metropolis; when the roar of the rushing business world momentarily subsides, we can distinguish the wail of misery. As we descend in the scale of property-owning, we find that difficulties increase until we reach the point where poverty becomes a crime, punishable by the deprivation of one's liberty and of the right to hold together one's family.

In a recent number of the *New York World* it is stated that a homeless family were found sleeping in an old boat-house. The man had got out of work, his wife sickened, and they were set in the street for non-payment of rent. Dispossessed of everything, it can be imagined what must have been the life of these unfortunate outcasts. Perhaps they were not as provident as they might have been; were not "forehanded;" had not sufficiently learned the lesson of selfishness and of sharp practice in dealing with their fellows. Poverty results only in part from self-indulgence; for the thrift which enables a man to make a "good bargain" with his neighbor makes it a bad bargain for the neighbor; so that the failure to secure a competency is only a proof of the lack of high qualifications as a bargainer. And how relentlessly the world punishes the man who is not born smart or acquires smartness. In the case quoted, the child of the couple was sent to a Children's Home, and, as the husband had obtained work, he was allowed to go free with his wife.

Another man, found sleeping in a wagon, was "sent up" for a month as a vagrant.

THE DOSING MANIA.

INTEMPERANCE assumes many popular forms not directly assailable from prohibition and temperance society stand-points. Alcoholism, advertising its victims by unmistakable signs and symptoms, stands as the emblematic figure-head of indulgence, and is the chosen target of those who seek to crush this evil by law. Drug habits may eventually produce more horrible effects than alcoholism, but are more secretly practised and with less danger of immediate detection. Fortunately, the difficulty of constantly procuring the desired supply presents an obstacle to the popularity of this form of vice, but it is not an entire check to its pursuit. Opium or morphine and cocaine, taken at first for medicinal purposes, and continued till use becomes abuse, weave a web around the feet of the wretched victim, who becomes hopelessly entangled in slavery. Chloroform and chloral, by their soothing properties, ensnare their percentage of habitués; and so the list may be increased by the various hypnotics, anodynes and anti-spasmodics, often sought to induce sleep or to quiet excited nerves.

There are persons who, though they would regard with virtuous condemnation the hypodermic consolation of morphine, or the tippling of cologne spirits, or the binding up of shattered nerves with asafœtida, would, nevertheless, fail to recognize the fact that they, themselves, were addicted to the drug habit. This latter evidence of the foolishness of human nature is manifested in the general dosing mania which takes possession of certain classes of individuals. Sometimes, it is one particular sovereign remedy which is in favor, and which is applied for all sorts of complaints, for every member of the family, and at every season of the year. Like Patrick's potations of whiskey to keep out both the heat and the cold, this cure-all relieves alike whooping-cough or gout. Then, again, the mania consists in treating some fancied or real ailment with every available remedy in the pharmacopœia, till nothing but the remarkable toughness of the human anatomy saves the life of this devotee of drug tippling, and furnishes a commentary on the effectiveness of medicine in general.

When the drug fiend's system becomes so saturated as to be impregnable to all remedies, resort is had to the unconscious physician, who vainly endeavors to make the impression which he expects from the results usually following his treatment. Often, indeed, while following the course prescribed by the physician, these maniacs surreptitiously alternate his remedies with occasional doses of their own selection, and, when relief is not obtained, the doctor must shoulder the blame.

Reckless, indiscriminate dosing is conducive to disease and opposed to the theory of the practitioner, who considers the use of drugs only when regulated by skill and experience, as a valuable assistant to nature in restoring and preserving health. A. G.

CATHOLIC priest and Protestant minister unite in the cry for help in famine-stricken Ireland; but the landlords still deny the existence of poverty and unanimously demand their pound of flesh.

Letters to the Editor.

ABSENCE OF KIDNEY.

AT an autopsy held here recently upon the body of a man who died of enteritis, congenital absence of the left kidney and ureter was discovered. The right kidney was enlarged to nearly twice the normal size; but beyond simple hypertrophy the microscope showed no evidences of organic change. The right ureter was enormously enlarged, being at first mistaken for a part of the small intestine.

DRIED-BEEF POISONING.

IN THE TIMES AND REGISTER of September 6, Dr. McCann, of St Paul, reports a case of poisoning supposed to be from dried-beef. A similar case in my own practice, slightly antedating his, will, perhaps, make it more probable that the beef was the offending article.

At noon, June 10, 1890, I was called to visit the family of Mr. W., whose two daughters and nephew were supposed to have been poisoned. All were suffering from severe pains in the stomach and bowels, vomiting and purging, which was relieved by the following prescription:

℞.—Tr. opii camph. . . . . ℥iv.
Bismuth subnit . . . . . ℥j.
Mist. cretæ. . . . . ad ℥ij.
M.—S. Teaspoonful after each loose discharge, or every hour while in pain.

Inquiring as to the cause, the only article that each of the three had partaken of was chipped-beef and cream, but Mr. W. and his brother had also partaken freely of the same article; Mrs. W. being the only one who had not tasted it.

Being pressed to account for the fact that Mr. W. and brother felt no ill effects, I said, "you may be sick later," only four or five hours having elapsed since breakfast, and I cautioned them to be on the look-out for trouble, and produce vomiting at once if they had any distress in the stomach.

The next day Mr. W. told me that about five o'clock in the evening he was taken sick suddenly, just like the other members of the family, and that his brother was similarly affected between seven and nine o'clock in the evening. Mrs. W. suffered no inconvenience at all. The meat could not be obtained for examination, but was beyond a doubt the toxic agent.

The meat had been obtained from the store the day previous and nothing appeared wrong in preparing it; neither did any of the family notice anything peculiar in the taste.

What process had taken place which rendered it poisonous I do not know, but dried-beef deserves mention at least in the next work published on Toxicology.

ANOMALOUS CASES IN PRACTICE.

DELAYED UNION OF THE TIBIA.

IN THE TIMES AND REGISTER, Vol. V, page 280, I reported under the head of Anomalous Cases in Practice a case of transverse fracture of the lower portion of the upper third of the femur, treated with plaster of Paris dressings with good results. I now report the experience of a particular friend, Dr. E. J. Scruggs, of Montserrat, Mo., in a case where he used similar dressings, which shows some serious disadvantages in this mode of treatment. He says:

"I have a case of delayed union, which is just recovering—getting so he can put almost his entire weight on the affected limb. The patient, while riding on horseback some nine weeks ago, was kicked by a mule that was being ridden in front of him, the blow taking effect in the middle third of the tibia, causing a comminuted fracture; the fibula was not broken. We dressed the limb with a plaster splint, which remained on for thirty days. Upon removal we found there had been no inflammatory action, and the bone was just as I put it, except some rounding of the sharp points. I concluded it had been too thoroughly mobilized, so removed all splints and gave the patient a pair of crutches. After a few days reparative inflammation set in, and soon new bone was formed, and is becoming quite solid; the patient being a young man twenty-five years of age, robust and good family history. Delayed and non-union are rare in this bone."

CONGENITAL OCCLUSION OF THE RECTUM AND ANUS.

CASE II.—On July 20, Mrs. S., the mother of three daughters, residing six miles from town, gave birth to an average-sized son; forty-eight hours afterward it was discovered that the child could not defecate. I was immediately summoned, and, upon examination, found that it was a case of congenital occlusion of the rectum and anus. After explaining the nature of the case, and how it would have to be treated, the entire family and friends, with the exception of the father, objected to any surgical interference. As it was late in the evening, and the atresia giving rise to considerable colic and flatulence, I prescribed tinc. opii deod. in ⅓ to ½ drop doses every four or five hours, as indicated, and instructing them if they should conclude during the night on an operation to report to me the next morning, which they did in the affirmative. During the day, assisted by Dr. T. C. Clark, of Hamburg, Ia., I operated; the child being in excellent condition from slight narcosis induced by the anodyne taken previously. Placing it on its back on the leaf of a sewing machine, near a window, making the raphe a land-mark with a bistoury, I divided the abnormal bands crossing the anal site, which resembled cicatrices; passing the instrument in for about one inch, reaching the cul-de-sac, which terminated just above the internal sphincter ani muscle. Whilst dividing the skin and abnormal tissues the child strained quite hard, which assisted very materially as a guide in the operation. On entering the tube the meconium flowed quite freely; the child ceased crying, and seemed to enjoy his new condition. There was no hemorrhage, nor injury done to the urethra or sphincter ani muscles, although I did not use a sound, as recommended by some authors. After the cutting was done Dr. Clark passed a dilator into the incision, stretching the parts until we felt assured that the abnormal tissues were well broken down. The child has enjoyed excellent health since the operation; its bowels have never given it any trouble. The third day afterwards I visited the patient, and used a dilator in order to ascertain the condition of the case, which was unnecessary, as the meconium was keeping the parts from adhering, and in good order—patient scarcely complaining when evacuating its bowels.

SIDNEY, IOWA.

MACKENZIE, the chess-player, is dying of phthisis.

Book Notices.

DRS. BOURNEVILLE AND BRICON'S MANUAL OF HYPODERMIC MEDICATION. Translated by G. ARCHIE STOCKWELL, M.D., F. Z. S. Physician's Leisure Library. George H. Davis, Detroit, Mich., 1890. Pp. 158. Cloth, 50c., paper, 25c.

This is a useful little book on a subject of importance to every practitioner.

VIRCHOW'S ARCHIVES OF PATHOLOGICAL ANATOMY, PHYSIOLOGY AND CLINICAL MEDICINE.

No. 3 of Vol. X of Eleventh Series, contains a contribution in part on The Congenital Fistulæ of the Neck: Their Anatomical Significance, and Relations to Allied Bronchial Defects. By K. Von Kostanecki and A. Von Mielecki, of the Berlin Anatomical Institute.

They present a full history of the literature of the subject, and notice the fact that though congenital, they do not always present an external opening at birth, but sometimes a swelling which soon breaks, forming an external opening, and sometimes this swelling and the subsequent opening are delayed to puberty, and in at least one recorded instance, to the age of thirty.

Dr. Richard Wagner, of Halle, furnishes The Mid-position of the Vocal Chord in Paralysis of the Recurrent Laryngeal Nerve. He recites several series of experiments and their results. In some of these experiments he cut the recurrent laryngeal alone, in others the superior laryngeal alone, in others both, in others the recurrent laryngeal and the crico-thyroid muscle. He draws the conclusion that the primary mid-position is due to the action of the crico-thyroid alone (the superior laryngeal supplying this muscle), and not to the fact that the fibres reaching the crico-arytenoideus posticus are more superficial, and therefore earlier affected than those of the adductors supplied by the same nerve; not to fibres from the superior laryngeal reaching the other muscles through the recurrent laryngeal; not to the existence of a special centre for the fibres of the recurrent which go to the crico-arytenoideus posticus, which are the views that have been, up to this time, generally advanced and accepted.

Dr. Alexander Favre contributes On White Infarctus of the Human Placenta, tracing connections between fœtal endarterites presenting thickened intima due to cell proliferation, organized masses of fibrin, debilitating general diseases, and inflammatory uterine diseases preceding pregnancy, and the condition in question.

Dr. G. Armauer Hausen, of Beyen, writes on the question, Is Leprosy Contagious? and as a result of investigation of the disease in Sweden, the Sandwich Islands and North America, ends with these words: "The result of my observations are in happy harmony with my theoretical conclusions, and I consider rather clearly established that leprosy is not a contagious disease."

Prof. S. M. Lukjanow, of Warsaw, contributes On the Influence of Partial Excision of the Liver on the Biliary Secretion, detailing a series of experiments with a view to its determination. He concludes that on removal of from 19 to 43 per cent. of the liver, no change in the character of the bile secreted, as to either the watery or solid constituents, can be made out.

Writing on Perforating Ulcer of the Nasal Septum, Dr. M. Hajek, of Vienna, describes the pathological process minutely, as commencing in the mucous membrane, with a diphtheria-like exudate, resulting in exfoliation, and consequent deprivation to the cartilage of its source of nutrition, which leads to necrosis and thus to perforation. He regards the disease as most frequently of a tubercular nature.

Dr. Walter Kruse, of Naples, writes on Blood Parasites. He finds parasites in the blood of frogs, inhabiting the red corpuscles, for the entrance of which he cannot account, as he finds them in no other parts. The organisms resembled most closely the Gregainida Bütschli.

The Medical Digest.

FRENCH NOTES.

BY A. E. ROUSSEL, M.D.

CEREBRAL ABSCESS WITH EPILEPTIC ATTACKS CURED BY TREPANNING.—M. Hans Schmid, of Stettin, presented a patient cured of cerebral abscess. His patient had received a severe wound over the parietal bone which, after having suppurated for a long time, was cured with the exception of the existence of a narrow fistula.

Six weeks after the injury there occurred the first attack of epilepsy, which was soon followed by others of greater frequency.

An examination revealed the possibility of an abscess under the skull, communicating exteriorly by the sinus, which discharged a sero-purulent liquid.

Trepanning was performed. An abscess existed, in effect, situated in the substance of the brain.

The cure was complete, and the epileptic attacks have completely disappeared.—*Bull. de Thér.*

COUNTER-INDICATIONS OF ANTIPYRINE.—Antipyrine is counter-indicated:

1. In all cases of feeble heart.
2. In diphtheria, when we have indications of the existence of myocarditis.
3. After profuse hemorrhage.
4. During menstruation, and in dysmenorrhœa.
5. In broncho-pneumonia in general, and in fibrous pneumonia complicated by pulmonary œdema.
6. In the last stages of pulmonary phthisis.
7. In all cases of extreme feebleness and emaciation, and in the advanced stages of chronic fevers.

—*L'Union Médicale.*

CREASOTE IN THE TREATMENT OF DISEASES OF THE RESPIRATORY ORGANS.—(*a*) For inhalations:

℞.—Creasote,
Chloroform,
Alcohol.....āā equal parts.

From five to twenty drops in atomizer; repeat these inhalations every three hours.

℞.—Iodoform..... 21 grains.
Creasote..... 4 drops.
Oil of eucalyptus..... 6 "
Chloroform..... 48 "
Alcohol,
Ether.....āā q. s. to make ½ ounce.

Five to twenty drops in atomizer; to be used every three hours.

(*b*) For internal use:

℞.—Creasote..... 24 drops.
Glycerine..... 1 ounce.
Syrup of orange flower..... 1 "

One teaspoonful every three hours.

℞.—Creasote,
Tincture of capsicum.....āā 10 parts.
Mucilage of gum Arabic..... .. 15 "
Distilled water..... 120 "
One teaspoonful, well diluted, at meal time.

—*La Bulletin Médical.*

INJECTION FOR GONORRHŒA (Brou).—

℞.—Opium..... 50 centigr.
Pulverized catechu..... 20 "
Saffron..... 1 gr.
Boiling water..... 200 gr.

Make infusion, filter, and add:

℞.—Acetate of lead (crys.)..... 1 gr. .50.
Sulphate of zinc (crys.)..... 3 gr.
M.—Sig. For injections.

POMADE FOR ALOPECIA (Monin).—

℞.—Gallic acid..... 3 grammes.
Essence of lavender..... 15 drops.
Vaseline..... 40 grammes.
Castor oil..... 20 "
M.—Sig. Apply with friction.

—*Journal de Maladies Cutanées.*

WINE OF CASCARA SAGRADA:—

1. ℞.—Fluid extract of cascara sagrada... 1 part.
Sherry wine..... 9 "
M.—Filter.

2. ℞.—Cascara sagrada..... 1 part.
Sherry wine..... 10 "
Macerate for eight days, press and filter.

These wines are administered in doses of a wine-glassful and over as a laxative.

ARISTOL IN GYNECOLOGY:—

1. ℞.—Aristol..... 5 grammes.
Oil of vaseline.....q.s.

Dissolve and add:
Gum Arabic,
Glycerine.....q.s.
to make five crayons three centimeters long.

2. ℞.—Aristol..... .50 to 1 gr.
Oil of cacao.....q.s.
